BILATERAL TUBAL LIGATION
BY MINILAPAROTOMY
UNDER LOCAL ANESTHESIA

Facilitator’s Guide
BILATERAL TUBAL LIGATION
BY MINILAPAROTOMY
UNDER LOCAL ANESTHESIA
Facilitator’s Guide
FOREWORD

The Department of Health, with its commitment to the delivery of quality care in family planning services, is strengthening the training system in acquiring knowledge and skills. In line with this, the training manual on Training on Bilateral Tubal Ligation By Mini-Laparotomy under Local Anesthesia (MLLA) has been updated with the goal of implementing a national standardized training of health workers across all regions in the country. It is expected that with the revised training manual on MLLA, service provision on MLLA will improve performance indicators on FP and subscribe to the achievement of quality FP services for the conduct of training on female voluntary surgical contraception. The updated evidence-based information on voluntary surgical sterilization (VSC) technique was adapted to further enhance service provision.

The manual contains the important topics and essential components of teaching and learning the standardized MLLA technique. The topics include counseling, voluntary decision making thru informed consent, the surgical procedure, provision of local anesthesia, infection prevention and control, post-operative and management of complications. The overall objective of the manual is to build the competence on the knowledge and skills of health providers on female sterilization by MLLA anchored on a more receptive, responsive and sensitive attitude towards future clients or acceptors.

I encourage the dissemination and use of this manual by health service providers in the conduct of training to expand the provision of VSC services for females through increased number of competent BTL-MLLA providers across the country to address the unmet need for women of reproductive age, thereby contributing to the attainment of MDG 5 under Universal Health Care.

ENRIQUE T. ONA, MD, FPCS, FACS
Secretary of Health
ACKNOWLEDGEMENT

The Department of Health acknowledges stakeholders and partners who have contributed their time and expertise to the development of this training manual on mini-laparotomy under local anesthesia. Their input and expertise have contributed significantly in shaping the performance and quality improvement approach in this manual.

The MLLA Technical Working Group contributed to completing this manual. They are:

- Dr. Cynthia Garcia, Consultant
- Dr. Francis Floresca, Private Sector Mobilization for Family Health – Phase 2 Project, USAID
- Dr. Rebecca Ramos, Health Policy Development Program, USAID
- Dr. Jocelyn Ilagan, Health Policy Development Program, USAID
- Dr. Esmeraldo Ilem, Jose Fabella Memorial Hospital
- Dr. Luis Garcia, Jr., Friendly Care
- Dr. Gerardito Cruz, Consultant
- Dr. Cesar Maglaya, Consultant
- Dr. Bernabe Marinduque, University of the Philippines – Philippine General Hospital
- Dr. Edna Abcede, Center for Health Development (CHD) – Central Luzon
- Dr. Casimiro Bacungan, Region 1 Medical Center

The Department of Health enjoins all to ensure the successful utilization of this standard training manual in the development of good quality BTL-MLLA service providers in both public and private sectors. This manual serves as the resource manual in achieving the DOH goal of provision and quality voluntary surgical sterilization services through the established training system across the country.

The following were also consulted for their inputs, sharing of their experiences as service providers as well as support from CHD staff:

- Dr. Cherry Pangilinan, Vicente Sotto Memorial Medical Center
- Dr. Distancy Montejo, St. Anthony Maternal and Child Health
- Dr. Gay Gonzales, Zamboanga Medical City
- Dr. Jun Boto, Jose Rodriguez Memorial Hospital
- Ms. Aurora Doria, PHO, Pangasinan
- Ms. Teresita dela Cruz – CHD Central Luzon
- Dr. Jovette Guinal – CHD Central Visayas
- Ms. Armi dela Cruz – CHD Ilocos

JANETTE LORETO-GARIN, MD, MBA-H
Undersecretary of Health
Support to Service Delivery Technical Cluster IV

TRAINING DESIGN

Course Description

This five-day competency-based clinical skills training course is designed to enable the trainee to perform standardized bilateral tubal ligation by minilaparotomy under local anesthesia (BTL/MLLA) procedure in their FP service provision. The course consists of didactic sessions and practicum phase spread out in the five-day duration. The first three days are conducted at the training site where didactics and practicum are conducted. The last two days are onsite practicum. The practicum for the BTL/MLLA technique involves demonstration and return demonstration using pelvic models proceeding with actual clients after competency in the models is attained.

Goals

The goal of the training course is to have a pool of BTL/MLLA service providers equipped with:

- knowledge, skills and attitude in performing the standard procedure of BTL/MLLA;
- knowledge and skills needed to prevent, recognize and manage complications related to the BTL/MLLA procedure; and
- knowledge, skills and attitude to integrate BTL/MLLA services into their existing service delivery system.

Specific Objectives

At the end of this five-day course, the trainee will be able to:

- apply the principles of counseling and informed consent for BTL/MLLA;
- explain the indications and precautions for BTL/MLLA based on the WHO Medical Eligibility Criteria for contraceptive use;
- practice infection prevention measures in the provision of BTL/MLLA services;
- perform complete screening evaluation of BTL/MLLA clients including pelvic examination as part of assessment;
- perform with competency the standard BTL technique of minilaparotomy under local anesthesia;
- recognize and manage surgical and anesthesia-related complications;
- provide routine follow-up management of side effects and other health problems related to minilaparotomy under local anesthesia; and
- develop an action plan on the integration of BTL/MLLA services into his/her practice.
Training/Learning Methods

- Illustrated lectures and discussions
- Individual and group exercises
- Case studies
- Demonstration and return demonstrations
- Simulated practice with anatomic (pelvic) models
- Guided clinical activities on pre-operative assessment and minilaparotomy under local anesthesia

Training Materials

- Facilitators’ Guide
- Participants’ handbook which also serves as a reference manual
- Powerpoint slides
- Pelvic models (ZOE) for simulated practice
- Minilaparotomy kits

Trainers

Trainers of the course must be obstetricians or surgeons in CHD-accredited training institutions/facilities who are:

- Proficient in performing abdominal/pelvic surgeries and are skillful in preventing and managing surgical complications
- Proficient in performing DOH standard BTL/MLLA procedure.
- Proficient and committed to providing training on BTL/MLLA
- Willing to coach trainees during their practicum and post-training monitoring and follow-up in their respective facilities
- Certified trainers on BTL/MLLA

Training site

- Training sites are CHD-accredited FP training centers particularly for VSC with certified trainers on BTL/MLLA.
- Training sites should have available clients for the practicum phase.
Trainees Selection Criteria

Trainees to this course must be doctors of medicine with experience in performing abdomino-pelvic surgery and who are:

- Affiliated with facilities where BTL/MLLA can be performed in accordance with DOH standards.
- Supportive of Family Planning, interested in being trained on BTL/MLLA and committed to regularly performing BTL/MLLA after the training.

Methods of Evaluation

Trainee

- Attendance
- Pre- and post-test
- Participation in discussions
- Performance of the skills on BTL/MLLA using the “Performance Checklist on Minilaparotomy Under Local Anesthesia”

Course

- Course evaluation accomplished by participants

Course Duration

The course duration will be for five days with didactic and practicum sessions spread out within the five-day course. The training site should ensure that there are enough clients for BTL/MLLA (at least 10 intervals and five postpartum clients for the course duration) for competency-based learning. In scheduling training, there should be collaboration with the CHD/PHO regarding demand generation to meet the case load during training or for that matter for the trained team to start up service provision in their catchment area.

Course requirement includes:

- Minimum number of cases prepared\(^1\)
- Number of trainees will depend on the number of trainers and case load.
- The training institution in coordination with CHD and PHO will prepare at least five intervals and five postpartum clients.

Suggested Course Composition

\(^1\) Applicable even for competency-based training
• 1:5 trainer/trainee ratio during the didactic part
• 1:1 trainer/trainee ratio during the clinical practice on actual clients
• Minimum of three and maximum of five trainees (depending on the number of trainers and case load)

Post-training Monitoring and Evaluation
A post-training monitoring and evaluation is conducted two months after training to assess the performance of the trainee. The purposes of this follow-up are to:

• Assess the on-the-job performance of the trainee
• Provide technical assistance to improve the knowledge and skill of the trainee
• Support the trainee and help resolve problems or answer questions
• Recommend for certification trainees who are able to satisfactorily apply learned skills
• Evaluate the results of training on the inclusion of BTL/MLLA services in the trainee’s facility (e.g., increase in client load for FP, utilization of services)

The frequency of conducting the evaluation depends on the need of the trainee and of his/her facility towards successful integration of quality BTL/MLLA services.

Certification
A Certificate of Competency is awarded by the training institution to trainees who have satisfactorily and competently completed the requirements of the five-day course (i.e., complete attendance, passing score in the post-test, and satisfactory skills rating based on the skills checklist as observed during the BTL Day practicum in his/her site). The regional director, the chief of hospital of the training institution and the trainer will be the signatories of the certificate.

After the post training monitoring and evaluation, a certificate as service provider will be issued upon successful integration of BTL/MLLA into his/her professional practice in her affiliated hospital/s. For the certificate to be issued, the provider should have performed at least 30 procedures in three months.

If competency is not achieved within the five-day course as a service provider, the trainee should be provided with more case load either in the training institution or in their own facility until the desired level of competency is reached and certificate of competency can be given. A certificate of attendance will temporarily be issued after the five-day training course if the skills requirement were not met.

After training, two to three sets of minilap kits are distributed per facility. These should be issued to their institutions, not to the service provider. Retractors and uterine elevators should be routinely included in the BTL kits.

Session 1

INTRODUCTION

OVERVIEW

Worldwide, female sterilization is used by 33% of married women using contraception, making it the most common contraceptive method for couples who desire permanent limitation of pregnancy. Tubal ligation is a good option for women seeking out a safe, effective, permanent and convenient form of contraception. Bilateral tubal ligation is the most common form of surgical sterilization procedure for tubal occlusion.

This session provides the service provider with basic information on BTL to enable him/her to provide accurate, evidence-based information on BTL/MLLA which is the DOH-approved standard procedure.

LEARNING OBJECTIVES

At the end of the session, the participants will be able to:

1. Discuss basic information on BTL
   - What it is
   - Mechanism of action
   - Effectiveness
   - Possible side effects
   - Warning Signs of Complications
2. Describe minilaparotomy as an efficient approach to BTL
3. Explain the reason for preferring MLLA for BTL
4. Provide evidence based facts in responding to myths on BTL

PREPARATION

- PowerPoint slides on “Introduction”
- Computer and projector
- Metacards
- Easel sheets
- Markers
- Tapes

TIME ALLOTMENT: 1 hour 30 minutes
### Bilateral Tubal Ligation by Minilaparotomy under Local Anesthesia

<tr>
<td></td>
<td>A safe and simple surgical procedure to tie and cut the 2 fallopian tubes located on both sides of the uterus.</td>
</tr>
</tbody>
</table>
State the mechanism of action and the effectiveness of BTL.

Mechanism of Action

The fallopian tubes, which carry eggs from the ovaries to the uterus, are blocked so that the woman's egg cannot meet the man's sperm.

Effectiveness

99.5% in the first year of use

Ask participants to write on metacards the advantages of BTL.

Remind participants on the correct use of metacards:

- One idea per metacard
- 5-7 words
- Large letters

Ask participants to post their metacards on the board.

Review with the participants each posted card.

Ask for clarification for unclear ideas.

If participants have exhausted the advantages comprehensively enough, there is no need to present the slides. Otherwise, review the items on the slides with participants.

Disadvantages

- Requires minor surgery
- Compared with vasectomy, BTL is:
  - Slightly more risky
  - Often more expensive
- Considered to be permanent
- If pregnancy happens (very rare), there is a greater risk for ectopic pregnancy compared to women who have not undergone the procedure
- Does not protect against STIs, including HIV/AIDS

Present the "Disadvantages of BTL" and elaborate on these, as needed.
### Possible Side Effects & Potential Problems

- **Related to surgical procedure:**
  - Pain and swelling over the operative site (diminishes in a day or two)

- **Other potential problems:**
  - Wound infection
  - Post-operative fever
  - Bladder, intestinal injuries (rare)
  - Hematoma
  - Pain at incision site
  - Superficial bleeding

### Minilaparotomy Under Local Anesthesia

**Description**

- An abdominal surgical approach to the fallopian tubes by means of an incision less than 5 cm. in length
- Also called “minilap”
- Safe, effective technique that can be performed on an out-patient basis under local anesthesia
- Reduced risk for anesthesia-related complications due to the use of local anesthesia
- Appropriate for interval and postpartum tubal occlusion

---

**Tell participants that:**

- The DOH-approved procedure for BTL is minilaparotomy under local anesthesia (BTL/MLLA)
- Describe BTL/MLLA as presented on slide.
### Timing of Procedure

**Related to pregnancy:**
- **Postpartum**
  - Within 48 hours = subumbilical procedure
  - Day 3-6 = procedure depends on size of the uterus
  - Day 8-41 = ML-LA not recommended
- **Postabortion** = suprapubic procedure

**Unrelated to pregnancy**
- **Interval** = suprapubic procedure

State at what times BTL/MLLA can be performed.

### Incision Sites

Describe the incision sites for BTL/MLLA.

### Why ML-LA?

- Ensures broad access to female sterilization because ML-LA:
  - Does not require sophisticated equipment that is expensive to purchase, maintain, and repair.
  - Requires few laboratory examinations and preoperative tests.
  - Can be performed by physicians with general surgical skills rather than requiring specialists.
  - Does not require an anesthesiologist.
- Highly effective, safe, able to be performed as an ambulatory procedure, and economical

Explain the reasons for preferring BTL/MLLA for BTL.

### Addressing Common Myths on Bilateral Tubal Ligation

Ask participants to write on metacards myths/misconceptions on BTL that they have heard.

Post the metacards on the board.

Write the myths in the manual on metacards. Add these to others posted by the participants.

Divide participants into groups of three. Distribute the metacards to the groups.
**ADDRESSING COMMON MYTHS and MISCONCEPTIONS**

**Group Work**

<table>
<thead>
<tr>
<th>MYTH</th>
<th>FACT</th>
<th>MESSAGES</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Ask each group to write on easel sheet the fact and counseling messages for each of the myths assigned to them using the following template:

Provide 15 minutes for the groups to complete the task.

A member of the group presents the group output in plenary.

Members of the other groups and facilitator supplement the presenting group's output.

**Conclusion**

**Conclusion**

- What significant information have you learned?
- What is the significance of the information/learning to you?
- How will you use the information in your service provision?

Conclude the session by reviewing the learning objectives of the session. For each of the objectives, ask a participant at random:

- what significant information he/she has learned relevant to the objective?
- what is the significance of this information/learning to him/her?
- how can he/she use the information in his/her practice?
BILATERAL TUBAL LIGATION

BTL is known as female sterilization as it provides permanent contraception for women who do not want any more children. It is a safe and simple surgical procedure to tie and cut the two fallopian tubes located on both sides of the uterus. The fallopian tubes carry eggs from the ovaries to the uterus. With the fallopian tubes blocked, the woman’s egg cannot meet the man’s sperm.

The effectiveness of BTL depends partly on how the tubes are blocked but pregnancy rates are very low. The procedure is 99.5% effective in preventing pregnancy.

BTL has the following advantages:

- Permanent; a single decision leads to lifelong, safe prevention of pregnancy
- Nothing to remember, no supplies needed, and no repeated clinic visits required
- No interference with sex; does not affect the woman’s ability to have sex
- Increased sexual enjoyment because no need to worry about pregnancy
- Has no hormonal side effects
- No effect on breast milk
- No known long-term side effects or health risks
- Can be performed just after a woman gives birth (immediately and within seven days after childbirth)
- For interval cases, can be done six weeks after delivery
- Can be performed at any day of the menstrual cycle provided you are reasonably sure that the woman is not pregnant

However, it has the following disadvantages:

- Requires minor surgery
- Considered to be permanent as reversal surgery is difficult, expensive and success cannot be guaranteed
- If pregnancy happens (very rare), there is a greater risk for ectopic pregnancy compared to women who have not undergone the procedure
- Does not protect against sexually transmitted infections including HIV/AIDS
There are no long-term side effects of BTL. A common side effect is pain over the operative site which diminishes in a day or two.

Problems affect women’s satisfaction with BTL. It is, therefore, important that the service provider attends to clients complaining of warning signs of complications and immediately refer her to a facility or health service provider who can assess and address her complaint.

### WARNING SIGNS
- Bleeding, pain, pus, heat, swelling or redness of the wound that becomes worse or is persistent. These are signs of infection of the incision site.
- High grade fever is a sign of more severe infection.
- Fainting, persistent light-headedness, or extreme dizziness
- Missed period, which signifies pregnancy

### MINILAPAROTOMY UNDER LOCAL ANESTHESIA FOR BTL

Minilaparotomy is a modified and simplified version of conventional laparotomy which was developed so that bilateral tubal occlusion services could be safely provided efficiently and at minimal cost. It is a safe, effective, flexible technique that can be performed on an outpatient basis under local anesthesia, and is appropriate for interval and postpartum tubal occlusion.

Interval cases are performed when the client is not pregnant (from at least 42 days after the last delivery). This greatly expands the opportunities for performing the procedure, however, timing is important to minimize the risk of undetected pregnancy. The procedure can be performed at any time the service provider is reasonably sure that the client is not pregnant.

Postpartum tubal ligation offers the advantage of convenience. The client is usually already in the facility where the procedure will take place, and recovers simultaneously from both the procedure and delivery without significant increase in discomfort and or length of stay. The decision to undergo postpartum tubal ligation should be made prior to the onset of labor whenever possible; information about this option should be a part of routine prenatal counseling. Postpartum clients may be transported to a facility where this procedure can be performed if there are no conditions that call for a delay or require precautions that the facility cannot handle. Timing issues for this procedure take into consideration the need to assess the condition of both mother and child after delivery, and the increasing difficulty of the procedure with time. Ideally, the procedure takes place within 48 hours postpartum. The uterine fundus is close to the umbilicus at that time, within reach of a subumbilical incision, and hospital stay is not prolonged. The procedure is possible up to the sixth day postpartum although the site of incision will vary depending on the level of the uterine fundus. Because the procedure becomes difficult with increasing contraction of the uterus, tubal ligation is not recommended from seven to <42 days postpartum.

Minilap tubal ligation can also be performed immediately or up to two weeks following a first trimester abortion if there are no signs of infection or other possible complications, and the uterus is no larger than 12 weeks in size. For second trimester abortions, it is necessary to wait until the uterus has involuted sufficiently – in general, after four weeks.
All candidates for minilaparotomy will require a standard medical screening, including complete history, physical examination, and assessment for anemia. Clients undergoing interval or post-abortal procedures will need to have a bimanual examination, which is usually not necessary in women immediately postpartum.

**ADDRESSING COMMON MYTHS ON BTL**

Acceptance of this safe and effective method, like the BTL, depends on the service provider being able to respond adequately to myths on the method. Presented in the table below are common myths on BTL that the service provider must be able to counteract to provide correct information on the method. Recommended counseling messages are provided to guide the service provider in responding to these myths.

| Causes irregular or heavier menstrual bleeding or amenorrhea | Most researches find no major changes in bleeding patterns after BTL. If a woman was using a hormonal method or IUD before sterilization, her bleeding pattern will return to the way it was before she used these methods. For example, women switching from combined oral contraceptives (COCs) to BTL may notice heavier bleeding as their monthly bleeding returns to usual patterns. Note, however, that a woman’s monthly bleeding usually becomes less regular as she approaches menopause. | • Menstrual periods will continue because this procedure does not remove the uterus and the ovaries. It only affects the tubes.  
• Menstruation comes from the uterus.  
• BTL does not affect menstrual bleeding since the ovaries are still functional and the uterus produces normal monthly periods. Problems of menstrual bleeding are usually caused by a hormonal imbalance, which is the result of a change in a woman’s health and her psychological feelings.  
• Changes could be caused by obesity, menopause, or hormonal imbalances.  
• For older women irregularities are more likely due to the normal aging process, not because of sterilization. For women who used COCs prior to sterilization, irregularities may be due to the transition from regulated to non-regulated cycles. Evidence, to date, does not support any biological explanation for an association between tubal ligation and subsequent menstrual or other gynecological problems.  
• Cessation of menses occurs as a result of age-related hormonal

| Only women of a certain age or who have a certain number of children can undergo BTL | All women can undergo BTL safely with proper counseling and informed consent. There is no justification for denying sterilization to a woman because of her age, the number of her pregnancies or living children, or her marital status. Health care providers must not impose rigid rules about age, number of children, age of last child, or marital status. If a specific woman's situation suggests to a provider that she could have regrets later, the provider should help the woman think through her decision carefully. Ultimately, however, each woman must be allowed to decide for herself whether or not she will want more children and whether or not to undergo sterilization. | • This is not true. BTL is for women who do not want any more children, have completed having the number of children they desire, and for health reasons (that is, for women where pregnancy is not recommended for medical reasons).  
• BTL is a safe procedure for most women, even if they are old or young, have just given birth, have only one or no children or they are still breastfeeding. Women must consider their choice because BTL is a permanent contraceptive method, which means once she decides to undergo sterilization, she will never have a child in the future.  
• The method can be used at any age, but the client must be absolutely sure that she doesn’t want any more children before she chooses sterilization because it is generally not reversible. If the client has doubts, she can use other temporary methods of contraception.  
• BTL is a personal decision. It is up to the woman to choose the method. Any woman who meets the medically accepted conditions may undergo the procedure. According to the World Health Organization (WHO), there are no medical reasons that permanently restrict eligibility for sterilization. However, there are medical conditions that may limit when, where, or how the BTL procedure should be performed. |
<p>| Causes a decrease or loss of sex drive or                             | After sterilization, a woman will look and feel the same as before. There is no loss of sexual drive | • There is no evidence to prove that BTL affects one’s sexual desire. A comfortable intercourse is usually |</p>

<td>related to the environment and a person’s physical and mental health.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Sexual desire is a psychological process and is hormone dependent. The female sex hormones which affect sexual drive are produced and released by the ovaries. When a woman undergoes sterilization, it is only her tubes that are blocked. Her other functions remain perfectly the same. In most cases, sexual pleasure increases due to freedom from the anxiety of pregnancy.</td>
</tr>
<tr>
<td>Causes long-term health risks (e.g., chronic pain and hormonal imbalance)</td>
<td>There are no documented long-term medical side effects of BTL. The few complications that do occur during or following sterilization, such as infection or abscess of the wound, can generally be kept to a minimum if appropriate techniques are used and if performed in an appropriate setting. Local anesthesia is best for BTL because it has lower risks of complications than use of general anesthesia. Female hormones are not affected by BTL, and there will be neither a loss of femininity nor any change in sexual functioning.</td>
<td>• Because there won’t be any intervention in the genital organs and sex hormones, there will not be any changes in your sex drive and sexual pleasure.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• The most common problem of sexual dysfunction is a psychological problem. For perimenopausal women, sexual function may be due to a disturbance or hormonal changes.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Sterilization is a simple surgical procedure that involves tying or severing the fallopian tubes so that the egg/ova and sperm are unable to meet and fertilize. The procedure does not cause long-term effects such as backache, weakness, or other illnesses or side effects. If the client experiences any of these symptoms long after the procedure, she should be referred for further evaluation. These may be due to other medical conditions that need to be investigated.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Backaches and abdominal pain are due to many other reasons. BTL does not cause such problems and the majority of women feel better after this procedure because they</td>

| Causes changes in weight (i.e., loss or gain) | Sterilization does not cause any changes in weight, appetite, or appearance. However, older women are more likely to choose sterilization for contraception than younger women and most women gain weight as they age. | are permanently free from the repeated threat of pregnancy.  
• BTL is only a minor procedure and the side effects are just minimal after the operation. It doesn’t cause health risks or side effects that may result in hysterectomy, poor health, pain or hormonal imbalances.  
• The most common side effect is regret due to a poor decision made by the couple.  
• BTL is a surgical procedure, not a hormonal contraceptive. Although the tubes are cut, there is no hormone produced or released from that part. It means your hormone function remains as usual.  
• BTL does not cause any health problem apart from infertility.  
• Weight changes are related to diet and lifestyle (less activity). Many women gain weight or lose weight without having BTL. In general, some women may experience weight changes at an older age due to metabolic changes.  
• Weight gain may also be related to the feeling of ease due to the release from the fear of pregnancy. |
Session 2

ORIENTATION TO COUNSELING

OVERVIEW

For women who no longer desire fertility, BTL is a safe and highly effective option. However, future regret in undergoing permanent contraception among clients may be encountered. It is, therefore, important that clients are counseled properly. With appropriate client selection and counseling, this problem is minimized.

This session provides the service provider with adequate information on proper counseling to minimize regret after undergoing BTL.

LEARNING OBJECTIVES

At the end of the session, the participants will be able to:

1. Define FP counseling
2. State the benefits of counseling
3. Explain the responsibilities of the counselor
4. Discuss service delivery requirements related to counseling (e.g., who counsels, and when and where performed)
5. Discuss important steps in counseling clients for VSC
6. Explain characteristics of clients likely to regret
7. Clarify the concern on reversal

PREPARATION

- PowerPoint slides on “Orientation to Counseling”
- Computer and projector
- Whiteboard and appropriate marker
- Metacards
- Tapes

<tbody>
<tr>
<td>Introduction</td>
<td>Introduce the topic by providing an overview to the session.</td>
</tr>
</tbody>
</table>

### Orientation to Counseling

#### Learning Objectives
- Define FP counseling.
- State the benefits of counseling.
- Explain the responsibilities of the counselor.
- Discuss service delivery requirements related to counseling (e.g., who counsels, and when and where performed).
- Discuss important steps in counseling clients for VSS.
- Explain characteristics of clients likely to regret.
- Clarify the concern on reversal.

#### Definition
Two-way communication to help clients explore their reproductive needs, so they can make voluntary, informed, and well-considered decision compatible with their needs.
### Basic Elements

- Involves 2-way communication between the counselor and the client
- Provides information and helps the client apply the information to his or her individual needs and circumstances
- Helps the client make informed and voluntary decisions about fertility and contraception
- Helps the client to safely and effectively use the contraceptive method he or she chooses

### Benefits of Counseling

#### Benefits to Clients

- Helps the client make an informed, voluntary, and well-considered decision
- Increases client satisfaction and continued use
- Increases likelihood of correct use of the chosen method
- Minimizes the possibility of postoperative dissatisfaction and regret

Emphasize the definition of “counseling” by presenting its “basic elements” and explanation for each of the elements, as follows:

- Involves two-way communication
  This is an interaction between the counselor and the client.
- Provides information on FP methods as relevant to the client’s needs and circumstances.
  Only FP methods relevant to the client’s needs are discussed. For example, if the client’s reproductive need is that of spacing, the permanent methods are not discussed.
- Based on the information the counselor provides as relevant to the client’s expressed needs and circumstances, the client decides whether or not to practice contraception and what method to use. **The client decides**; not the counselor.
- When the decision on what method to use is made, the counselor provides instructions to the client on how to access and use the method.

Ask participants to write on metacards their ideas on the benefits of counseling to clients then to the program.

For each of the brainstorming exercises, review the metacards and summarize the inputs. The slides may be used to supplement and summarize the inputs.
### Benefits to the Program

- Enhances reputation of the program and its staff as clients increase
- Contributes to higher rates of contraceptive continuation
- Improves the quality of the program

### Responsibilities of the Counselor

- Identify client’s reproductive & contraceptive goals
- Gain insight into the client’s medical, obstetrical, and contraceptive history and personal circumstances
- Find out what the client knows about the contraceptive methods
- Provide whatever information the client lacks
- Corrects the client’s misconceptions about methods

- Answer the client’s questions and address his/her concerns
- Help the client come to a decision about her fertility and contraception
- Help the client apply information about methods to her individual situation.
- Explain to the client how to get or use the method she chooses
- Ensure that the client is not making a decision because of pressure from any person, policy, or incentive
- Ensures privacy and confidentiality

### Service Delivery Requirements

Present the “Service Requirements” for counseling.
Ask participants their ideas for the inputs.
Bilateral Tubal Ligation by Minilaparotomy under Local Anesthesia

Who Can Counsel

- Health workers trained on effective FP counseling

In programs offering sterilization services, ensuring that the client has made a free, informed decision is ultimately the responsibility of the surgeon.

Who Can Counsel
• Health workers trained on effective FP counseling
In programs offering sterilization services, ensuring that the client has made a free, informed decision is ultimately the responsibility of the surgeon.

When To Conduct Counseling

- In labor
- During CS
- In stressful situations (e.g., in pain)

At any time the client desires, when the client is able to clearly comprehend the information, and when her judgment is not impaired.

When To Conduct Counseling
• In labor
• During CS
• In stressful situations (e.g., in pain)

Tell participants that:
- Though the surgeon does not perform FP counselling, it is his/her duty to ensure that the client has been properly counselled.

Ask participants:
- Based on information as to when it is appropriate to do counselling, is it effective to do counselling:
  - During labor?
  - During CS?
  - During stressful situations?

Important Steps in Counseling for VSC

- Assess knowledge on FP and the methods
- Provide key information about sterilization
  - what it is, what it entails, its consequences, availability of alternative FP methods
  - BTL does not affect normal sexual function, or physical and mental health
  - possible risks and side effects
  - intended permanence of sterilization with slight possibility and consequences of failure

Discuss the “Important Steps in Counseling for VSC”.

Tell participants that:
- Though the surgeon does not perform FP counselling, it is his/her duty to ensure that the client has been properly counselled.

Ask participants:
- Based on information as to when it is appropriate to do counselling, is it effective to do counselling:
  - During labor?
  - During CS?
  - During stressful situations?

Discuss the “Important Steps in Counseling for VSC”.
### Important Steps in Counseling for VSC

- Assure that change in decision is acceptable without sacrificing her or her family's right to other services
- Assess psychological readiness to undergo sterilization
  - listen to client carefully
  - collect information about client's personal circumstances and feelings about ending fertility

### Client Characteristics Associated with Regret

The following characteristics suggest additional/extensive counseling:

<table>
<thead>
<tr>
<th>Characteristics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Being young</td>
</tr>
<tr>
<td>Having few or no children</td>
</tr>
<tr>
<td>Having children of same sex</td>
</tr>
<tr>
<td>Having a child in poor health</td>
</tr>
<tr>
<td>Spouse disagrees with procedure</td>
</tr>
<tr>
<td>Being single or widowed</td>
</tr>
<tr>
<td>Pressure from others</td>
</tr>
<tr>
<td>Under unusual stress</td>
</tr>
<tr>
<td>Making decision quickly</td>
</tr>
<tr>
<td>Lacking access to other FP methods</td>
</tr>
<tr>
<td>Making decision under influence of Incentives</td>
</tr>
<tr>
<td>Being incompletely or incorrectly informed about sterilization</td>
</tr>
<tr>
<td>Undergoing procedure because of medical conditions</td>
</tr>
</tbody>
</table>

### Concerns on Reversal

- Reversal, if available, involves complicated and difficult surgery which makes the procedure costly
- Not ALL are qualified for reversal because of factors like age, fertility impairments, type of BTL performed
- Functional success is variable with high risk of ectopic pregnancy

### Ask participants:

- What client characteristics are associated with regret?

Write responses on white board.

Summarize by presenting the slide on the subject.

### Tell participants that:

- Though BTL can be reversed, it must be considered as a permanent method.

Present the “Concerns on Reversal”.

Elicit participants’ ideas.
### Conclusion

**Conclusion**

- What significant information have you learned?
- What is the significance of the information/learning to you?
- How will you use the information in your service provision?

---

Respond to participants’ questions on the subject.

Review the learning objectives for the session.

For each objective, call on participants at random to respond to the following questions:

- What significant information he/she has learned relevant to the objective?
- What is the significance of this information/learning to him/her?
- How can he/she use the information in his/her practice?
WHAT IS FAMILY PLANNING COUNSELING?

Although this term has different meanings in different cultures, and in some languages the word does not exist, many would agree that the concept of family planning counseling includes four basic elements:

- It helps the client to make informed and voluntary decisions about fertility and contraception.
- It involves two-way communication between the counselor and the client.
- It provides information and helps the client apply that information to his or her individual needs and circumstances.
- It helps the client to safely and effectively use the contraceptive method he or she chooses.

Counseling family planning clients is a different way of communicating for many health providers. Doctors, nurses, and other professionals with medical or health training are accustomed to giving advice to patients who need treatment. Unless there is health reason precluding a method of contraception, the choice of a method is a matter of personal preference. Counseling is more than just giving clients information. It requires asking questions and listening. It involves two-way communication and aims to help clients make their own decisions. Counseling should be objective, and the counselor should avoid expressing bias for or against any family planning method. Motivation should not be confused with counseling. Motivation is subjective; its messages consist of information emphasizing the benefits of what method is being promoted.

It is acceptable to motivate people in general to use family planning, but it is not acceptable to promote only one particular method. This violates the individual's right to make a decision and choose the best option for himself or herself. All staff can benefit from a basic understanding of the purpose of counseling and the importance of a client's right to informed choice.

WHAT IS INFORMED DECISION MAKING?

Informed decision making is the desired result of the counseling process through which a client makes a well-considered, voluntary decision about contraceptive use. This decision should be based on options, information, and an understanding of the risks of pregnancy and sexually-transmitted infections (STIs) and the levels of protection provided by different contraceptive methods, including the understanding of relevant medical facts and the potential risks involved while using contraceptives— and, more importantly in the case of BTL, about the procedure and its effects and about the risks and benefits associated with the surgery. This information should be tailored to individual clients, filling gaps in their knowledge, correcting any misinformation, and addressing their questions and concerns. Clients should be able to make a real choice among contraceptive options that are offered and explained. They should also receive information about BTL’s lack of protection against STIs, including HIV, and they should be aware that dual protection may be advisable in some situations.

WHY IS COUNSELING IMPORTANT?

Benefits for the Client

Helping the clients understand and resolve concerns related to contraception is important to ensuring s/he will make an appropriate choice. Studies have shown that clients are most likely to continue a
method and to use it correctly if they have chosen it themselves. Therefore, it is important for clinic staff to let clients select a method that they feel will work for them.

Counseling benefits clients interested in any kind of contraception (as well as other reproductive health concerns).

- It helps the client make an informed, voluntary, and well-thought decision.
- It can increase client satisfaction with the method plus continued use.
- It increases the likelihood that the client will use the chosen method correctly.

Counseling is particularly important for clients who are considering permanent methods.

- Clients considering sterilization are faced with making a decision that will permanently affect their fertility.
- Effective counseling helps minimize the possibility of postoperative dissatisfaction and regret.

**Benefits to the Program**

- Counseling improves the quality of the program.
- It can enhance the reputation of the program and its staff, which will help retain clients and attract new ones.
- It may contribute to higher rates of contraceptive continuation.

Family planning providers sometimes resist the notion of counseling because they believe their programs, already financially strapped and understaffed, cannot afford to allocate resources to this activity. The cost of providing counseling is ultimately less than the cost of not doing so. If family planning clients are not prepared for method side effects, they are likely to discontinue use and express their resulting dissatisfaction to friends and neighbors. If many clients who choose permanent contraception ultimately regret their decisions, this is likely to have repercussions in the community. In either circumstance, the family planning program’s reputation will suffer, and clients will stop coming for services.

**RESPONSIBILITIES OF THE FAMILY PLANNING COUNSELOR**

A fundamental goal of every family planning program should be to have its clients make free and informed decisions about their fertility. Program staff must provide all family planning clients, including those interested in sterilization, with the information necessary to make a reasoned, voluntary decision about their fertility. The information must be in the language and terminology that the client can understand. The family planning counselor should encourage questions, and should answer them clearly and directly in terms the client can easily understand. Clients should know of the benefits and risks associated with those available temporary and permanent methods of contraception in which they are interested. The counselor should discuss effectiveness, and common side effects of these methods, to help clients determine the suitability of methods to meet their reproductive preferences and life circumstances.

It is the counselor’s responsibility to do the following:

- Identify the client’s reproductive and contraceptive goals.
• Gain insight into the client’s medical, obstetrical, and contraceptive history and personal circumstances.
• Find out what the client knows about contraceptive methods.
• Provide whatever information the client lacks.
• Answer the client’s questions and address his/her concerns.
• Help the client come to a decision about her fertility and contraceptive use.
• Identify and correct the client’s misconceptions about methods.
• Help the client apply information about methods to her individual situation.
• Explain to the client how the contraceptive method she chooses will work and the proper use of the method.
• Ensure that the client is not making her decision because of pressure from any person, policy, or incentive.
• Explain to the client how she can get the contraceptive and refer if necessary.
• Ensure privacy and confidentiality.

SERVICE DELIVERY REQUIREMENTS RELATED TO COUNSELING

Who Can Counsel

A doctor, nurse, educator, or other health worker can be trained for and carry out family planning counseling. Effective counseling requires special training and good interpersonal communication skills. In programs offering sterilization services, regardless of who does the counseling, ensuring that the client has made a free, informed decision is ultimately the responsibility of the operating doctor.

Where Can Counseling Be Done

If at all possible, counseling should be conducted in a private area. Given the personal and confidential nature of information, which may be discussed, it is important to provide as much privacy as possible (limiting interruptions). Even where there are physical limitations to designating a private space, providers should try creative approaches to give clients privacy (for example, by using curtains, screens, outside spaces, low voices, etc.).

When to Conduct Counseling

Counseling may take place at any time the client desires and when the client is able to clearly comprehend the information. A client choosing minilaparotomy needs time to reflect on her decision before the procedure, and should not make the decision when her judgment may be impaired. As a rule, counseling is not appropriate or effective, nor should informed consent documents be signed, when a woman is sedated, in labor, or experiencing stress or pain before, during, or after a pregnancy-related event or procedure. It is preferable for clients interested in postpartum minilaparotomy to receive counseling well in advance of the pregnancy-related event. Clients desiring sterilization following spontaneous or induced abortion may need to delay the procedure unless they had decided on the sterilization well in advance of the abortion.
COUNSELING CLIENTS INTERESTED IN MINILAPAROTOMY

Counseling enables the provider to assess what the client knows about family planning, to fill in any gaps in information or correct misinformation, and to help the client reach a firm and comfortable decision. Counselors need to provide key information about sterilization, to ensure that clients clearly understand what it is, what it entails, its consequences, and the availability of alternative contraceptives to control fertility. Counselors should tell clients that minilaparotomy does not affect normal sexual function, physical health, or mental health. It is important to give clients information about possible risks and side effects, but without scaring the client. The counselor stresses the intended permanence of sterilization as well as the slight possibility and consequence of sterilization failure (that is, pregnancy). The counselor discusses what to expect during and after surgery. Finally the provider must assure the client that she can decide against the procedure at any point without prejudicing the staff or sacrificing her or her family members’ right to other services.

Beyond providing information, the counselor should assess the client’s psychological readiness to undergo minilaparotomy sterilization by listening to her carefully, with particular attentiveness to signs of doubt, conflict, misunderstanding, or unrealistic expectations about the procedure. In view of the critical and sensitive nature of this decision, it is essential that the counselor collect information from the client about her personal circumstances and feelings about ending her fertility.

It is also important for the counselor to identify clients who are indecisive about undergoing surgery or concerned about reversal, and to advise such clients to consider the decision further. The following points are important to consider:

- Reversal, if available at all, involves complicated and difficult surgery, requiring specialized skill.
- Some individuals who request reversal may be inappropriate candidates because of age, fertility impairments, spouse’s infertility, or insufficient length of tube for reversal.

CLIENT CHARACTERISTICS ASSOCIATED WITH REGRET FOLLOWING STERILIZATION

Below is the list of some characteristics clients may have that suggest they may need additional counseling, since these characteristics have been associated with a higher rate of regret. The counselor should not use these factors as arbitrary grounds for denying sterilization to a client. Rather, the counselor should view them as signals that the client requires further counseling to be sure the client weighs the choice of sterilization and its alternatives.

- Being young
- Having few or no children
- Having a spouse who disagrees with the decision for sterilization
- Being single or widowed
- Being pressured by a spouse or someone else to undergo sterilization
- Making the decision under unusual stress (e.g., during labor)
- Making the decision quickly, without time to reflect and reconsider
- Making the decision under influence of payments or other incentives
- Lacking access to other methods of contraception
- Being incompletely or incorrectly informed about sterilization
- Undergoing sterilization because of medical indications

of doubt, conflict, misunderstanding, or unrealistic expectations about the procedure. In view of the critical and sensitive nature of this decision, it is essential that the counselor collect information from the client about her personal circumstances and feelings about ending her fertility.
• Even for clients who are suitable candidates for reversal, and even when a highly skilled surgeon using the most advanced surgical technique performs the reversal procedure, functional success (term pregnancy) is variable with a high risk of ectopic pregnancy.

• Reversal procedures are costly, and the requestor is usually responsible for the expense.

• Women who are advised to undergo sterilization because pregnancy poses a serious health risk for them are at high risk for regret. These women may not have chosen to end their fertility under other circumstances; thus, they need help to understand and accept why an end to childbearing is recommended. They must understand the dangers that pregnancy poses to them. Barring medical contraindications, effective, long-acting contraceptives—IUDs, injectables, Norplant implants, or vasectomy—should be presented as alternatives to women who do not want to undergo sterilization.

IN VOLVING THE SPOUSE OR PARTNER

Because sterilization is intended to end an individual's ability to have children, it is wise for the counselor to speak to both the client and her partner, if possible and if desired by the client. Clients should always have some time alone with the counselor. However, spousal consent should not be a prerequisite for receiving services unless it is a legal requirement.
Session 3

VERIFICATION OF INFORMED CONSENT

OVERVIEW

Bilateral tubal ligation is considered a permanent method. As such, it is the service provider’s responsibility to ensure that regret does not happen. The service provider must verify that the client has consented to undergoing the procedure based on important information to make a sound decision.

This session provides the service provider with adequate information on ensuring informed consent.

LEARNING OBJECTIVES

At the end of the session, the participants will be able to:

1. Define “informed decision-making” and “informed consent”.
2. Explain the importance of informed decision-making and consent.
3. Explain the elements of informed consent.

PREPARATION

- PowerPoint slides on “Verifying Informed Consent”
- Computer and LCD
- Whiteboard and appropriate marker
- Metacards
- Tapes

**Verifying Informed Consent**

**Learning Objectives**

- Define “informed decision-making” and “informed consent”.
- Explain the importance of informed decision-making and consent.
- Explain the elements of informed consent.

**Definition**

**Informed decision making**
- End-result of counseling in which the client makes a well-considered, voluntary decision about contraceptive use.

**Informed consent**
- Client’s written acceptance, agreement, or permission, based on his/her free will to undergo a medical or surgical procedure after having made an informed decision.
- For VSS, the client gives informed consent after being counseled, by signing (or by putting her thumb impression on) a consent form before the procedure is performed.
Importance

• Enhances the family planning program’s acceptability and credibility by reducing the incidence of client regret
• Protects the provider against allegations that the client did not choose sterilization voluntarily or was uninformed about the procedure, its consequences, risks, and alternatives

Ask participants:

• Knowing what “Informed decision making” and “Informed Consent” are, what do you think are the importance of these?

Call on participants.

Write responses on whiteboard.

Summarize the responses by presenting the slide on the subject.

Elements of Informed Consent

1. There are available temporary methods.
2. BTL is a surgical procedure.
3. The surgical procedure involves risks, in addition to benefits.
4. The effect of the procedure is permanent.
5. The procedure does not protect the client and his/her partner from STIs
6. The client can decide against the procedure at any time before the procedure.

Discuss the “Elements of Informed Consent” using the information on the slide. Elaborate as needed.

Provide copies of the “Informed Consent Form for Voluntary Sterilization”.

Discuss the contents of the “Informed Consent Form for Voluntary Sterilization”.

Informed Consent Form for Voluntary Sterilization

I, the undersigned, request that Tubal Ligation (Tubal Ligation) be performed on me. I understand that any risks involved have been explained to me.

I understand the following:
1. There are available temporary methods.
2. BTL is a surgical procedure.
3. The surgical procedure involves risks, in addition to benefits.
4. The effect of the procedure is permanent.
5. The procedure does not protect the client and his/her partner from STIs
6. The client can decide against the procedure at any time before the procedure.

I authorize the following:

______________________________
(Signature of patient)

______________________________
(Signature of operator)

______________________________
(Issuer of medical advice)

If the client cannot read, a witness to the client’s (if known) who is of the same sex and who speaks the same language as the client must sign the following declaration:

I, the undersigned, swear that the client has offered to be operated or not as is present.

______________________________
(Witness of patient)

______________________________
(Witness of operator)

Bilateral Tubal Ligation by Minilaparotomy under Local Anesthesia
NARRATIVE

INFORMED CONSENT AND COUNSELING

Counseling provides a client with information and an opportunity to discuss her decision about her fertility. Thorough counseling can help ensure that clients make free, informed, and well-thought decisions about their fertility. It is the staff's responsibility to furnish information the client needs to make such a decision, including information about ML/LA, other sterilization and anesthesia techniques offered, and other contraceptive methods. The staff must determine whether the client understands the consequences of, and is comfortable with, her decision. Staff must also determine if the client’s choice is voluntary. Counseling also diminishes the possibility of regret after sterilization, which is more likely to occur when a client is not fully informed, has not considered the consequences of her decision, or has not requested the procedure voluntarily.

Documenting a client’s informed consent is the final step in a process where the client has made a decision about a medical procedure, after weighing all the relevant facts. Documentation of informed consent takes place once the client has made a firm decision after counseling but before surgery.

Informed consent is the client’s voluntary decision, based upon a complete understanding of the relevant facts, to undergo a medical procedure, such as minilaparotomy. Consent is voluntary when the client gives it of her own free will and without inducement, force, fraud, deceit, duress, bias, or other forms of coercion or misrepresentation. Any payment to the client must be carefully considered as to whether it constitutes an inducement. The client cannot be considered to have made an informed decision unless she understands the important facts related to minilaparotomy. It is imperative that the client understands that temporary methods of contraception are available to her and her partner. She must also be aware that if the operation is successful, its effects are intended to be permanent and will prevent her from having children. Staff must also assure her that she can decide against the procedure at any time before the fallopian tubes are occluded, and that she will not sacrifice the right to other services at the clinic if she changes her mind.

INFORMED CONSENT: WHAT IT DOES NOT MEAN

Informed consent is not a replacement for counseling. The client’s signature on an informed consent form alone does not ensure that she has requested the operation willingly or was fully knowledgeable of the facts and available options. A client who signs an informed consent form under duress, or without fully understanding what she is signing or the nature of the operation and its effects, has not given informed consent.

WHY IS INFORMED CONSENT IMPORTANT?

Properly administered informed consent procedures are important to the service provider, as well as to the client. In addition, they may help enhance the family planning program’s acceptability and credibility by reducing the incidence of client regret. The signed consent document also helps protect the provider against allegations that the client did not choose sterilization voluntarily or was uninformed about the procedure, its consequences, risks, and alternatives.
THE RESPONSIBILITY OF THE DOCTOR

By the time she meets the doctor, the minilaparotomy client should have received counseling about her contraceptive options, made an informed decision to undergo ML/LA, and has signed a consent form. Even though other staff may have counseled the client and obtained her signature on the form, it is the responsibility of the doctor to verify informed consent by talking with the client before the procedure. Before starting any part of the procedure, including administration of sedative drugs, the doctor must be certain that the client’s decision is voluntary, informed, and well considered.

Below are the templates of Informed Consent Form (in English and Tagalog).
Informed Consent Form for Voluntary Sterilization

I, _________________________, the undersigned, request that Voluntary Surgical Sterilization – bilateral tubal ligation or vasectomy – be performed on my person. I make this request of my own free will, without having been forced or given any special inducement.

I understand the following:

1. There are temporary contraceptive methods available to me and my partner.
2. The procedure to be performed on me is a surgical procedure, the details of which have been explained to me.
3. This surgical procedure involves risks, in addition to benefits, both of which have been explained to me.
4. The effects of the procedure should be considered permanent.
5. The procedure does not protect me or my partner from infection with sexually transmitted infections, including HIV/AIDS.
6. I can decide against the procedure at any time before the operation is performed (without losing my right to medical, health or other services or benefits).

(Signature or mark of client) ............................................. (Date) .............................................

(Signature of attending doctor or delegated assistant) ............................................. (Date) .............................................

If the client cannot read, a witness of the client’s choosing who is of the same sex and who speaks the same language as the client must sign the following declaration:

I, the undersigned, attest that the client has affixed his thumbprint or mark in my presence.

(Signature or mark of witness) ............................................. (Date) .............................................
KASULATAN NG PAHINTULOT PARA SA PAGTATALI
(Tubal Ligation o Vasectomy)

Ako, si ________________, ang nakalagda sa ibaba, ay humihiling na gawin (pangalan ng pasyente)

sa akin ang pagtali sa pamamagitan ng paraang ________________. (isulat ang pamamaraan)

Ito ay ayon sa aking sariling kagustuhan, hindi ako pinilit o hinikayat. Nauunawaan ko ang sumusunod:

1. May mga pansamantalang pamamaraan ng kontrasepsiyon para sa akin at sa aking kabiya/kinakasama.

2. Ang pamamaraang gagawin sa akin ay isang simpleng pagtitistis o simpleng operasyon na ang
detalye ay ipinaliwanag sa akin.

3. Bukod sa mga ipinaliwanag na mga benepisyong pagtatali, nauunawaan ko na may bihirang
pagkakataon na nalalagay sa alanganin ang sumasailalim sa simpleng operasyong ito..

4. Kung magiging matagumpay ang operasyon, ang bisa nito ay permanente na at hindi na ako
maganaknak pang muli.

5. Ang operasyong ito ay hindi makapagbibigay sa akin at sa aking partner ng proteksyon laban sa
mga nakakahawang sakit sa pagtatalik, kabilang na ang HIV/AIDS.

6. Maari pa ako ng umurong sa pamamarang ito anumang oras bago simulan ang operasyon (alam
kong walang mawawalang benepisyong o anumang karapatan pangkalusugan o serbisyo kung
sakaling magbago ang aking desisyon).

Session 4

PREVENTION OF INFECTION

OVERVIEW

Thousands of BTL/MLLA take place throughout the world each year without serious complications of an infectious nature. Occasionally, however, life-threatening infections are associated with these procedures. They include tetanus, gangrene, and abdominal sepsis. Minor surgical wound infections are more common, but less-serious, infectious complications of minilaparotomy. The incidence of incurable blood-borne viruses, such as the human immune-deficiency virus (HIV) and hepatitis B virus (HBV), continues to rise. Because these viruses can be spread unknowingly (symptoms may take years to appear) and because it may not be possible to distinguish infected from uninfected individuals, appropriate infection prevention procedures must be practiced at all times and with all clients. It is important to realize that not only are the clients at risk of these infections, but so are the staff.

This session provides service providers with the knowledge on the internationally accepted and recommended infection prevention practices to decrease the likelihood of transmission of these infections in health care settings to either clients or staff.

LEARNING OBJECTIVES

At the end of the session, the participants will be able to:

1. Explain the concept of “standard precautions” in preventing spread of infection.
2. Discuss handwashing.
3. Enumerate the steps of proper handwashing.
4. Discuss the use of gloves.
5. Explain aseptic technique and its processes:
   - Surgical scrub
   - Using surgical gloves
   - Client preparation
   - Establishing and maintaining a sterile field
6. Discuss antisepsis and disinfection.
7. Differentiate antiseptics and disinfectants.
8. Discuss the steps in processing instruments and other items.
9. Discuss proper waste disposal.

PREPARATION

- PowerPoint slides on “Prevention of Infection”
- Computer and LCD
- Whiteboard and appropriate marker
- Metacards
- Tapes
- Examination gloves
- Paint
- Handkerchief for blindfolding

**TIME ALLOTMENT**

2 hours 30 minutes

**Learning Objectives**

- Explain the concept of “standard precautions” in preventing spread of infection.
- Discuss handwashing.
- Enumerate the steps of proper handwashing.
- Discuss the use of gloves.
- Explain aseptic technique and its processes:
  - Surgical scrub
  - Using surgical gloves
  - Client preparation
  - Establishing and maintaining a sterile field

**Learning Objectives**

- Discuss antisepsis and disinfection.
- Differentiate antiseptics and disinfectants.
- Discuss the steps in processing instruments and other items.
- Discuss proper waste disposal.

**Standard Precautions**

Consider every person as potentially infectious

![Image](image1.png)

Tell participants that:

- Standard precautions are based on the assumption that every person in the facility is considered as potentially infectious.
- Because many people with blood-borne viral infections (e.g., hepatitis B [HBV] or C [HCV], HIV) do not feel or look ill, standard precautions are to be applied consistently, regardless of the (known or unknown) health status of those who are providing or receiving care.
• When applied consistently, standard precautions act as protective barriers between microorganisms and individuals, and are considered a highly effective means of preventing the spread of infection.

• The following actions help to form such barriers, as well as provide the means for implementing the standard precautions:
  - Wash hands
  - Wear gloves
  - Use physical barriers
  - Process instruments, gloves, and other items
  - Safely dispose of infectious waste materials including sharps

Tell participants that:

- Handwashing is the most important procedure for preventing cross-contamination (person to person or contaminated object to person).

Discuss “Handwashing” as presented on the slides.

### Types of Handwashing

1. **With soap and running water**
   - Removes transient microorganisms and soil
   - Appropriate in most situations

2. **With antiseptic and running water**
   - Removes transient microorganisms and soil
   - Kills or inhibits resident microorganisms
   - Appropriate before invasive procedures

*Remember*

Alcohol handrubs do not remove dirt or organic material such as blood. If your hands are dirty, wash them with soap and running water.
When to Handwash

- Immediately when arriving at work
- Before and after examining each client
- After touching anything that might be contaminated
- After handling specimens
- Before putting on gloves for clinical procedures
- After removing any gloves
- After using the toilet or latrine
- Before leaving work

Steps of Handwashing

Ask for a volunteer from among the participants or call one at random.
Instruct the participant to put gloves on both hands.
Blindfold the participant and put paint on one gloved hand.
Instruct the participant to do his/her motions of handwashing for 30 seconds.
Remove the blindfold and ask the participant to show his/her hand to the class.
Call another participant to tell which parts of the gloved hand did not have paint.
Tell participants that those parts without paint were not washed properly.
Present the steps of handwashing as illustrated on the slide.

Tell participants that:

- Gloves are worn on both hands before touching wet broken skin, mucous membranes, blood or other body fluids (secretions and excretions), soiled instruments, and contaminated waste materials or for performing invasive procedures.

Present the slide on “Gloves”.

Use of Gloves
Gloves

- Protective barrier for provider and client
- Worn when there is danger of infection from hands or contaminated surfaces and materials
- Three types
  - Utility
  - Non-sterile, examination gloves
  - Sterile, surgical gloves

What gloves to wear

Ask participants:
- On which occasions do you wear gloves?
- What type of gloves do you wear for each of these tasks?

Run the slide and call participants at random to provide the answers.
Correct and provide the rationale for the appropriate answer for incorrect answers.

Aseptic Technique

Definition
Practices performed just before and during a clinical procedure that can help prevent infection.

Examples...
Step 1: Remove all jewelry from your hand and wrist.

Step 2: Wet hands and forearms thoroughly.

Step 3: Clean under each fingernail with a stick or brush.

Step 4: Hold your hands up so that they are higher than your elbow and apply antiseptic.

Step 5: Begin scrubbing at the fingertips of one hand and continue to the elbow. Be sure to scrub between fingers. Repeat for the other hand and arm.

Step 6: Continue scrubbing. Total scrubbing time should be 3-5 minutes.

Step 7: Rinse each arm separately, keeping your hands higher than your elbow.

Step 8: Using a sterile towel, dry your hands and arms working from the fingertips to the elbow. Use one side of the towel to dry the first hand and the other side of the towel to dry the second hand.

Surgical Gloves

- Worn for any procedure where hands will come in contact with the client’s bloodstream or tissues under the skin.
- Contaminated when:
  - Outside of the glove is touched with bare hands
  - Gloved hands touch anything that is not sterile
  - Gloved hands are held below the waist
Wearing Surgical Gloves

**Step 1:** Prepare a large, clean, dry area for opening the package of gloves. Open the outer and inner glove packages.

**Step 2:** Perform a surgical scrub.

**Step 3:** Pick up the first glove by the cuff, touching only the inside of the cuff.

**Step 4:** While holding the cuff, slip your other hand into the glove.

**Step 5:** Pick up the second glove by sliding the fingers of your gloved hand under the cuff. Be careful not to touch your gloved hand with your bare hand.

**Step 6:** Put the second on by maintaining a steady pull through the cuff.

**Step 7:** If necessary, adjust the glove fingers until the gloves fit comfortably.

Removing Surgical Gloves

**Step 1:** Rinse gloved hands in a basin of decontamination solution to remove blood.

**Step 2:** Grasp one of the gloves near the cuff and pull it off partway. The glove will turn inside out.

**Step 3:** With the first glove still over your fingers, grasp the second glove near the cuff.
**Removing Surgical Gloves**

<table>
<thead>
<tr>
<th>Step 4:</th>
<th>Pull off the first glove, being careful to touch only the inside surface of the glove.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 5:</td>
<td>If the gloves are disposable or are not intact, dispose of them immediately.</td>
</tr>
<tr>
<td>Step 6:</td>
<td>Wash hands immediately after gloves are removed, since the gloves may contain tiny holes.</td>
</tr>
</tbody>
</table>

**Client Preparation**

**Remember**
- Most client infections after surgery are caused by contamination during the procedure—not because clients do not keep the wound clean.
- Proper client prep with antiseptics before a procedure is critical.
- Shaving is no longer recommended. Clip hair that might interfere with the procedure.

**How to Prep Clients**

**For the skin**
- Make sure that the surgical site has been cleaned with soap and water.
- Apply antiseptic and gently scrub the skin in a circular motion—beginning in the center of the site and moving out—using sterile cotton balls, cotton wool, or gauze held by a sponge forceps.

**For the vagina, cervix, or other mucous membranes**
- Using sterile cotton balls, cotton wool, or gauze sponge held by a sponge forceps, apply antiseptic liberally before instrumentation.
- Do not use alcohol and alcohol-based antiseptics.

Present the slides on the guidelines on “Client Preparation”.

---

**Bilateral Tubal Ligation by Minilaparotomy under Local Anesthesia**

---
### How to Prep Clients
- Never leave cotton balls, cotton wool, or gauze sponges in antiseptic.
- Never dip cotton or gauze into the antiseptic container.
- Pour the amount of antiseptic needed into a small container and dip the cotton or gauze into it.
- Discard remaining poured antiseptic after client prep.

### Establishing & Maintaining a Sterile Field
- A sterile field is created by placing sterile towels or surgical drapes around the procedure site.
- A sterile field should also be established on the stand and table that hold sterile instruments and other items needed during the procedure.

### Guidelines
- Never set up a sterile field near the door or an open window.
- Items below the level of the draped client are outside the sterile field and is, therefore, considered unsterile.

### Maintaining a Sterile Field
- Allow only sterile items and personnel within the field.
- Do not contaminate sterile items when opening, dispensing, or transferring them.
- Consider the edges of the package holding a sterile item to be contaminated.
- Consider any sterile barrier that has been penetrated (wet, cut, or torn) to be contaminated.
- When in doubt of the sterility of an item, consider it as contaminated.
Bilateral Tubal Ligation by Minilaparotomy under Local Anesthesia

Present the slides on “Antisepsis”.

Define “Antiseptics” as written on the slide.

To check the participants’ understanding of antiseptics, ask them what antiseptics they have in their facilities.

Correct mistakes when disinfectants are included in their response.
### Antiseptic Solutions

- Chlorhexidine Gluconate (*Hibitane*, *Hibiscrub*, *Savlon*)
- Isopropyl alcohol (60-90%)
- Iodine (3%)
- Iodophors (*Betadine*)

### Antiseptic Solutions to Avoid

- Benzalkonium chloride (*Zephiran*)
  - Easily contaminated by *Pseudomonas* and other common bacteria, and are easily inactivated by cotton gauze and other organic material.
- Mercury laurels and other mercury-containing compounds
  - Dangerous because of their toxicity

Enumerate available antiseptics as presented on the slide.

Present the slide on “Antiseptic Solutions to Avoid”.

Present the slides on “Disinfection”.

### Disinfection

**Definition**

A process that eliminates most, but not all disease causing microorganisms from inanimate objects
To check the participants’ understanding on “Disinfectants”, ask them to give examples of these.

Emphasize that:
- Antiseptics are used for the skin and mucous membranes.
- Disinfectants are used for objects like floors, equipment, and instruments.

Discuss “Processing of Instruments and Other Items” as presented on the slides.

**Decontamination**

**Advantages**
- Kills dangerous viruses like hepatitis and HIV.
- Makes instruments and items safer to handle during cleaning.
- Makes cleaning easier because it keeps blood, fluids and tissue from drying.

**How to do**
- Soak items in a 0.5% chlorine solution immediately after use.
Decontamination

Preparing 0.5% Chlorine Solution from solution

Parts of water/part of chlorine
\[ \frac{\text{%concentrated chlorine}}{\text{desired chlorine concentration}} - 1 = \frac{1}{9} \text{ parts water/part of chlorine} \]

\[ \frac{1}{9} \text{ part chlorine in 9 parts water} \]

Preparing 0.5% Chlorine Solution from powder/granules

Grams of chlorine powder or granules/liter of water
\[ \frac{\text{desired concentration}}{\text{concentrate of granules}} \times 1000 \]

\[ \frac{.5}{30} \times 1000 = .0166 \times 1000 = 16.7 \text{ gms/liter} \]

17 grams of 30% chlorine granules/powder in 1 liter of water

Cleaning
Removes organic material (blood and tissue) and dirt that can interfere with processing. Also reduces the number of microorganisms.

High-Level Disinfection (HLD)
Eliminates all microorganisms except for bacterial endospores. May be through: boiling, chemical, and steaming.
Bilateral Tubal Ligation by Minilaparotomy under Local Anesthesia

Sterilization Eliminates all microorganisms. This makes this to be usually preferred over HLD. May be through steam, dry heat, and chemical.

After processing, items should be used immediately or stored so that they do not become contaminated. Proper storage is as important as proper processing.

Ask participants:
- What are the sharps in your facilities?

Hazards Associated with Sharps

In health care settings, injuries from “sharps”—needles, scalpel blades—are the #1 cause of infections to staff from bloodborne pathogens.
### Risks for Injuries from Sharps

- Recapping of hypodermic needles
- Bending or breaking needles
- Stuck by persons carrying sharps
- Sharps showing up in unexpected places, like linens
- Clients moving suddenly during injections

### Use of Multidose Vials

- Check the vial to be sure there are no leaks or cracks.
- Check the solution to be sure that it is not cloudy and no particulate matter.
- Wipe the top of the vial with a cotton swab soaked with 60-70% alcohol. Allow to dry.
- Use a new needle and syringe for each new person
  - Never use a contaminated needle or syringe that has been used previously
- Do not leave needles in multiple dose vials

### Waste Disposal

#### Kinds of Waste

- **General waste**
  - Non-hazardous waste. Poses no risk of injury or infection.
- **Hazardous medical waste**
  - Infectious
  - Pathological
  - Pharmaceutical
  - Chemical
  - Sharps
  - Pressurized containers
  - Genotoxic
  - Radiactive
  - Heavy metals
Four Steps of Waste Management

- **SORT**
  - Separate into non-hazardous (general waste) and hazardous (medical and chemical).

- **SAFE HANDLING**
  - Wear thick gloves when handling medical waste, wash hands after handling.

- **SAFE INTERIM STORAGE**
  - Area minimally accessible to staff, clients, visitors. Containers should have lids. Store no longer than 1-2 days

- **FINAL DISPOSAL**

### Sorting

<table>
<thead>
<tr>
<th>Trash Bag</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>BLACK trash bag</td>
<td>General, non-infectious, dry</td>
</tr>
<tr>
<td>GREEN trash bag</td>
<td>General, non-infectious, wet</td>
</tr>
<tr>
<td>YELLOW trash bag</td>
<td>Infectious, pathological</td>
</tr>
<tr>
<td>SHARP container</td>
<td>Sharps</td>
</tr>
</tbody>
</table>

### Disposal of Sharps

- Use sharps puncture proof containers.
- Burial is the safest way to dispose of sharps.
- Wash hands after handling sharps containers.
- Decontaminate and wash gloves.

### Hazardous Chemical Wastes
(disinfectants, glutaraldehyde, formaldehyde, cleaning solutions)

- Rinse containers thoroughly with water.
- Glass containers may be washed with detergent and water, and may be reused.
- Plastic containers should not be reused for holding solutions.
Final Disposal

**GENERAL WASTE**
- Dispose as with general rubbish

**SOLID MEDICAL WASTE**
- Best disposed of on premises
- Burning is best (not open burning)
- Burial
- Coordinate with hospitals for disposal

---

**Group Work**

<table>

Divide participants into groups of working in the same facilities.
Instruct the groups to discuss and fill out the template.

---

**Do You Have Any Questions??**

Ask participants for questions on the topic.
Respond to participants' questions and concerns on the topic.

---

**Conclusion**

**Conclusion**
- What significant information have you learned?
- What is the significance of the information/learning to you?
- How will you use the information in your service provision?

Review the learning objectives for the session.
For each objective, call on participants at random to respond to the following questions:
- what significant information he/she has learned relevant to the objective?
- what is the significance of this information/learning to him/her?
- how can he/she use the information in his/her practice?
NARRATIVE

STANDARD PRECAUTIONS

As health professionals, we cannot provide health care services without conducting procedures that put clients and staff at some risk of exposure to potentially infectious materials, but we can prevent transmission in many cases. The only way to prevent infections is to stop the transmission of microorganisms.

Standard precautions are based on the assumption that every person in the facility is considered as potentially infectious. Because many people with blood-borne viral infections (e.g., hepatitis B [HBV] or C [HCV], HIV) do not feel or look ill, standard precautions are to be applied consistently, regardless of the (known or unknown) health status of those who are providing or receiving care.

When applied consistently, standard precautions act as protective barriers between microorganisms and individuals, and are considered a highly effective means of preventing the spread of infection.

The following actions help to form such barriers, as well as provide the means for implementing the standard precautions:

- **Wash hands** – the most important procedure for preventing cross-contamination (person to person or contaminated object to person).
- **Wear gloves** (on both hands) before touching wet broken skin, mucous membranes, blood or other body fluids (secretions and excretions), soiled instruments, and contaminated waste materials or for performing invasive procedures.
- **Use physical barriers** (protective goggles, face masks, and aprons) if splashes and spills of blood or other body fluids are possible (e.g., when cleaning instruments and other items).
- **Use antiseptic agents** for cleansing skin or mucous membranes before surgery, cleaning wounds, or doing hand rubs or surgical hand scrubs with an alcohol-based antiseptic product.
- **Process instruments, gloves, and other items** after use by first decontaminating and thoroughly cleaning them, and then either sterilizing or high-level disinfecting (HLD) them, using recommended procedures. Again, in the context of IUD services, HLD is the recommended method of final processing.
- **Safely dispose of infectious waste materials** to protect those who handle them and prevent injury or spread of infection to the community.

HANDWASHING

Handwashing is one of the most important steps in prevention of the spread of infections. Routine handwashing is important before and after examining or having any direct contact with a client. Hands should be washed after touching any object that might be contaminated with blood or other body fluids. Hands should also be washed after removing gloves, since small holes or tears may be present.
Plain or antimicrobial soap should be used for routine hand washing and hands should be rinsed in a stream of running water, then dried with a clean towel or air-dried. Shared towels become easily contaminated and should not be used. Microorganisms can multiply in standing water even when a disinfectant is added; therefore, practices such as a common basin where multiple people wash their hands should be avoided.

**THE SURGICAL SCRUB**

Sterilized or high-level disinfected and holeless gloves are mandatory for the doctor and surgical assistants. Prior to putting on gloves, surgical staff must thoroughly scrub their hands with soap and water or antiseptic agents, for example, hexa-chlorophene, chlorhexidine, gluconate, or an iodophor. A small stick or a brush should be used for cleaning under the fingernails and a soft brush, cloth, or sponge should be used on all surfaces of the hands and forearms. For facilities where surgical scrubbing is accomplished with soap and water only, this should be followed by an ethyl alcohol and glycerin rinse (2-ml glycerin in 100-ml alcohol), rubbing the hands together until dry.

Ideally, the surgeon and his or her assistant should scrub thoroughly between procedures. In high-volume settings, this may not be feasible because the skin cannot tolerate the irritation caused by frequent scrubbing. In such settings, surgical staff should do a three-minute scrub every hour or after every four or five cases (whichever comes first), to prevent recolonization of the skin by microorganisms. Using 3–5 ml of the alcohol-glycerin mixture and rubbing the hands together until dry is an effective way to reduce numbers of bacteria on the hands between every case. Gloves must be changed between cases and when they are torn. Staff should wash their hands after removing their gloves when they leave the operating room for any reason or if gloves are torn. They should scrub before re-entering the operating room or before putting on another pair of gloves after having removed a torn pair.

Staff should wear short-sleeved shirts or scrub suits, have short and clean fingernails, and remove all jewelry. To scrub, hands should be held above the level of the elbows, thoroughly wet up to the elbows with water, and antiseptic solution applied. Beginning at the fingertips and using a circular motion, the hand and then arm up to the elbow should be vigorously washed. The procedure should be repeated for the other hand. While holding the hands above the elbows, the hands and forearms should be rinsed fingertips first. The entire procedure should be repeated several times, so that the scrub lasts three to five minutes overall. The hands and forearms should be dried with a towel.

**ANTISEPTIC SOLUTIONS**

Antiseptics are designed to remove as many microorganisms as possible without damaging or irritating the skin or mucous membrane on which they are used. Antiseptics usually do not have the same killing power as chemicals used for disinfection of inanimate objects. With the exception of iodine and alcohol, which are also disinfectants, antiseptic solutions should never be used to disinfect inanimate objects such as instruments and reusable gloves.

Below is a list of antiseptic solutions appropriate for surgical scrubbing and skin preparation prior to minilaparotomy. The most versatile solutions, which can be used for both surgical scrubbing and skin preparation, include alcohol, chlorhexidine gluconate, and iodophors. Chlorhexidine and iodophors are safe for use on mucous membranes and can be used to cleanse the vagina and cervix prior to insertion of a uterine elevator. Alcohol, iodine preparations, and hexachlorophene should not be used on mucous membranes. Descriptions of several recommended antiseptic solutions follow.
Chlorhexidine Gluconate

Chlorhexidine gluconate is an excellent antimicrobial for surgical scrub and skin preparation. It remains active against microorganisms on skin for as long as six hours after use, and is safe even for use on newborn infants. The recommended concentration, 4% chlorhexidine gluconate, is commonly available under the trade names Hibitane and Hibiscrub. (Note: Savlon, which contains chlorhexidine, is not listed because the concentration varies from country to country, from as little as 1–4%.)

Isopropyl Alcohol Solutions (60–90%)

Isopropyl alcohol (60–90%) are excellent antiseptics, commonly available, and inexpensive. It rapidly kills all fungi and bacteria, including mycobacteria, and kill most viruses, including HBV and HIV. Although alcohol has no persistent killing effect, the rapid reduction of microorganisms on skin protects against regrowth of organisms, even under gloves, for several hours. Alcohol can be used as a rinse after a surgical scrub with soap, as a rub between cases (in combination with glycerine), and for skin preparation; however, it should not be used on the cervix, vagina, or genitalia. A 60–70% solution of isopropyl alcohol is recommended because it is effective, less drying to the skin, and less expensive than higher strengths. Alcohol is not effective for cleaning and, as such, should not replace hand washing with soap and water.

Iodine Solutions

Iodines in a 3% concentration are highly effective antiseptics for skin preparation. Because they are irritating, they should not be used on the vagina, cervix, or genitalia. Iodines must be removed from the skin using alcohol to prevent irritation. Formulations of 1–3% iodine are available as both aqueous (Lugol) and alcohol (tincture of iodine in 70% alcohol) solutions.

Iodophors

Iodophors are solutions of iodine mixed with a carrier that releases small amounts of iodine. Unlike iodines, iodophors are generally nontoxic and nonirritating to skin and mucous membranes and can be used on the cervix, vagina, and genitalia. Iodophors kill vegetative bacteria, mycobacteria, viruses, and fungi. They require up to two minutes of contact time to release free iodine. Once released, however, the iodine has rapid killing action. It is not usually necessary to dilute commercially available iodophors manufactured for antisepsis. Povidone iodine is the most common iodophor. Iodophors are available under the trade names Betadine and Wesodyne.

SOLUTIONS TO AVOID

Benzalkonium chloride (Zephiran) is not an effective surgical antiseptic because solutions may become contaminated by Pseudomonas and other common bacteria, and are easily inactivated by cotton gauze and other organic material.

Mercury laurels and other mercury-containing compounds, which may be sold as antiseptic, are dangerous because of their toxicity. Skin exposure may result in absorption of mercury, blister formation, and contact dermatitis. Inhalation or ingestion of low levels of mercury may cause central nervous system disorders (numbness, speech impairment, and deafness) and higher levels (200 mg or more) may be fatal. Pregnant women exposed to small doses may not show toxic effects themselves, but their fetuses may be harmed.
PROCEDURES FOR PREOPERATIVE PREPARATION OF THE PATIENT

Proper preparation of the client for surgery helps prevent infection. The client should change from street clothes into a clean gown. If the client is unable to bathe or shower on the day of the procedure before coming to the clinic, the operative site should be thoroughly washed with soap and water before applying the antiseptic. The staff should evaluate the client for signs of local infection in the operative area. If the client has a local infection, the operation should be postponed, the infection treated, and a form of temporary contraception provided.

It is best not to shave the hair near the operative area. Shaving results in nicks in the skin where bacteria may proliferate, leading to an increased potential for postoperative infections. If hair obstructs the operating area, it should be trimmed just before the operation to reduce the time for potential proliferation of bacteria.

The performance of a careful pelvic examination is essential before tubal occlusion, and can detect the large majority of cases of active pelvic infection. High-level disinfected gloves and speculum should be used for the pelvic exam. It is not necessary that these items be sterile. For interval procedures, the vagina and cervix are cleansed with antiseptic solution before insertion of the uterine elevator. Employ the no touch technique in inserting the uterine elevator. Recommended antiseptics are iodophors (such as Betadine) and chlorhexidine. Iodophors require one to two minutes to work, because there must be time for the release of free iodine, which inactivates the microorganisms. Antiseptic solutions should be liberally applied, at least two times.

Using disinfected, dry forceps to hold antiseptic-soaked cotton, a staff member thoroughly cleans the abdominal site by gentle scrubbing. The solution is applied in a circular motion at the site of the incision from the inside working out, for several inches around the site. A circular motion inhibits immediate recontamination of the site with local skin bacteria. Excess antiseptic should not be permitted to drip and gather beneath the client’s body, as this may cause irritation. After the surgical site is disinfected, the area should be covered with a sterile drape.

USE OF MULTIDOSE VIALS

Specific guidelines must be followed to prevent contamination of multidose vials. A needle must never be used to draw up a solution from a multidose vial once it has been used for a client’s injection unless the entire contents of the vial are to be used only on the one patient or the needle has been processed. Likewise, after a syringe is used for an injection, it must not be used again to withdraw more solution from a vial. Changing the needle but using the same syringe that has been used to give an injection to another client is not a safe practice. Hepatitis B virus has been shown to be transmitted from one patient to another under such circumstances. Do not leave needles in the multidose vials as these cause contamination.

Syringes larger than 10 ml is not often available. If more than 10 ml of a solution from a multidose vial is needed, staff can use the same needle and syringe to withdraw the solution in 10 ml doses, depositing each dose into a sterile medicine cup on the surgical stand. During the administration of the solution, the required amounts can be withdrawn from the supply in the cup. Because the solution from the cup will be used on only one patient, it is not necessary to change the needle and syringe each time more solution is drawn up from the cup. Any solution remaining after the procedure should be discarded. This is a useful procedure to follow for local anesthesia for minilaparotomy where up to 20 ml of 1% lidocaine will be used. An additional advantage to this method is that the chance of overdose is virtually eliminated, because no more than the maximum dose is made available for use.
**PROCESSING OF INSTRUMENTS AND OTHER REUSABLE ITEMS**

**DECONTAMINATION**
- Soak in 0.5% chlorine solution for 10 minutes

**CLEANING**
- Wearing gloves and appropriate personal protective equipment, thoroughly wash and rinse to remove all blood and tissue from instruments.

**STERILIZATION**
- **Chemical**
  - Glutaraldehyde 2% 10 hrs
  - Formaldehyde 8% 24 hrs
- **Autoclave**
  - 106k Pa (15lb/in²) pressure, 121°C (250°F)
  - Unwrapped: 20 min, Wrapped: 30 min
- **Dry Heat**
  - 170°C for 60 min

**HIGH-LEVEL DISINFECTION**
- **Boil or Steam**
  - Completely covered (immersed), at rolling boil, with a lid on, for 20 min.
- **Chemical**
  - Glutaraldehyde 2% 20 min
  - Formaldehyde 8% 20 min
  - Chlorine: 0.1% (prepared using boiled water) for 20 min.

**Cool and Use Immediately**
- OR
**Store Properly**

*Wrapped sterile packs can be stored for up to one week. Unwrapped items should be stored in a sterile or high-level disinfected container with a tight fitting lid or used immediately.*

Decontamination and cleaning of instruments and other items followed by sterilization or high-level disinfection can minimize the risk of transmitting infections to both the client and health care worker. Because high-level disinfection does not reliably destroy all bacterial endospores, instruments and other items for use during surgical procedures should be sterilized. When it is not possible to use sterilization, high-level disinfection is the only acceptable alternative for processing instruments and other items for reuse.

**Decontamination**

Surgical instruments, reusable gloves, and other items that have been in contact with blood or other body fluids should be decontaminated prior to cleaning. **Immediately after use**, items should be placed in a plastic bucket containing a solution of 0.5% chlorine for 10 minutes. Chlorine rapidly inactivates both HBV and HIV, making the instruments safer for staff to handle during cleaning. After
10 minutes, items should be removed from the chlorine solution and rinsed with water or cleaned immediately. Soaking instruments for excessive periods of time in the chlorine solution is damaging to the instruments. It is best to wear utility gloves during this and subsequent steps. A new chlorine solution should be prepared at the beginning of each day. Ideally, there should be separate containers for sharps (scalpel blades, suture and hypodermic needles), instruments, and gloves. Gloved hands should be immersed in chlorine solution prior to removal and should be inverted as removed and deposited in chlorine solution.

**FORMULA TO CALCULATE AND MIX APPROPRIATE CHLORINE SOLUTION**

**From concentrated solution:**

\[
\text{Total parts Water} \quad (\text{for one part concentrated chlorine}) = \frac{\% \text{ Chlorine in concentrated solution}}{0.5\% \text{ (desired concentration)}}
\]

Example: To make a 0.5% chlorine solution from a 5% concentrated Chlorine solution: (following the formula)

\[
\text{Parts water} = \frac{5\% \text{ Cl}}{0.5\%} = 10 - 1 = 9
\]

Use 1 part concentrated chlorine solution and 9 parts water

**From dry powder:**

\[
\frac{\text{Weight (grams) dry powder}}{\text{Liter of water}} = \frac{\% \text{ desired concentration}}{\% \text{ concentrate powder}} \times 1000
\]

Example: To make a 0.5% chlorine solution from a 35% concentrated chlorine powder

\[
\text{Grams} = \frac{0.5\%}{35\%} \times 1000
\]

\[
= 14.2 \text{ grams/liter}
\]

**Cleaning**

Cleaning is a crucial step in instrument processing and greatly reduces the number of microorganisms and endospores on instruments and other equipment. Before equipment is high-level disinfected or sterilized, a thorough mechanical cleaning is necessary to remove blood and organic material. This material can interfere with the high-level disinfection and sterilization process because microorganisms in and under it may not be killed. Both sterilization and HLD procedures are not effective without prior cleaning. Instruments should be vigorously scrubbed using a brush in soap and warm water to completely remove all blood, tissue, and other residue particularly in the hinges, joints and grasping surfaces. Instruments are rinsed thoroughly with water as soap may interfere with further processing. Items are allowed to air-dry. Items to be high-level disinfected by boiling can be directly placed in a pot of water.
High-Level Disinfection

High-level disinfection is effective in eliminating all microorganisms except some bacterial endospores. It is appropriate for instruments that will be in contact with unbroken skin or mucous membranes, such as uterine elevators, specula, and gloves for pelvic examinations. High-level disinfection is the only acceptable alternative for processing instruments and other items for reuse if sterilization is not possible. To be effective, high-level disinfection must be preceded by decontamination, careful cleaning, and thorough rinsing. High-level disinfection can be achieved by immersing items in boiling water for 20 minutes or by soaking items in a chemical disinfectant such as a 2% glutaraldehyde (Cidex), 8% formaldehyde solution or in a 0.5% chlorine solution for 20 minutes, then rinsing with boiled water. Nothing should be added to or removed from the water or chemical solution once timing has begun. Following either procedure, if items are not used immediately, they should be air-dried and stored in a covered, high-level disinfected container for up to one week. Alcohol, iodine, and iodophors are not considered high-level disinfectants. Storage and rinsing containers must also be sterilized or high level disinfected. For rinsing solutions, this should be done daily, for dry storage, weekly. Labels giving date of processing should be placed in the containers.

Sterilization

Sterilization eliminates all microorganisms (bacteria, viruses, fungi, and parasites) including bacterial endospores from instruments and other items. Sterilization is recommended for items that come in contact with the blood stream or tissues beneath the skin such as reusable needles, syringes, and surgical instruments. Sterilization can be achieved by using steam (autoclaving) or dry heat (oven) or by soaking in a chemical solution. To be effective, sterilization must be preceded by decontamination, careful cleaning, and thorough rinsing.

It is best to wrap equipment before steam sterilization with paper or double-layered cotton fabric. Items or packs should be arranged in the autoclave to allow free circulation of steam. Wrapped items should be sterilized for 30 minutes; unwrapped items for 20 minutes, at 121°C (250°F) and 106 kPa pressure (15 lb./in.)2. Packs or items should be allowed to dry before removing them from the autoclave and to cool before storage or use. Wrapped items can be stored for up to seven days. Unwrapped items should be used immediately or stored in a covered sterile container for up to seven days. The sterilization process should be monitored to be sure that the equipment is truly sterilized. This is best accomplished by use of a reliable biological indicator containing live bacterial spores, at regular intervals. The autoclave itself should be checked with each use to make sure it is functioning properly, and repairs should be made when necessary (for example, broken gauges and seals should be replaced).

It is best to wrap equipment in foil or double-layered cotton fabric prior to sterilization by dry heat. Items or packs should be sterilized at 170°C (340°F) for 60 minutes or 160°C (320°F) for 120 minutes. Timing should not begin until the oven has reached the desired temperature. Because dry heat can dull sharp instruments and needles, these items should not be sterilized at temperatures higher than 160°C. Items should be allowed to cool before removing them from the oven. Wrapped items can be stored for up to seven days. Unwrapped items should be used immediately or stored in a covered sterile container for up to seven days.

To achieve chemical sterilization, items should be soaked for at least 8–10 hours in a 2% glutaraldehyde solution (for example Cidex) or 24 hours in 8% formaldehyde solution. Items should not be added or removed once timing has begun. Items should be rinsed well with sterile water, air-dried, and stored in a covered sterile container for up to seven days.

Storage of Processed Items

Proper storage of high-level disinfected and sterilized items is equally as important as the high-level disinfection or sterilization process itself. Items should be stored dry. Microorganisms will multiply
in standing water even if a disinfectant has been added. For this reason, the practice of storing pick-up forceps in a bottle filled with disinfectant solution should be avoided. It is more appropriate to high-level disinfect the forceps each day and store them dry, in a high-level disinfected wide-mouth cylindrical container. If possible, items should be stored in an enclosed cabinet. An item must be considered contaminated when the package is torn or damaged, when the wrapping is wet, or when the expiration date is exceeded.

**FACILITY REQUIREMENTS**

Operating staff who are ill, or have infections, or draining lesions or cuts on exposed areas should be excluded or assigned other duties out of the operating room until they are well.

**Operating Room**

The operating room should have a tile or concrete floor that can be easily and thoroughly cleaned. It should be enclosed, free of dust and flies, have adequate lighting, and be well isolated from the part of the clinic or hospital that is open to the public. The operating room should be locked when not in use and should not serve as a storeroom. Ideally, the operating room should be air-conditioned. Windows should be 1.8 m (6 ft.) above the floor or high enough to prevent cross-ventilation in the operative field, and should be screened against flies and mosquitoes. If there is a problem with insects, the room should be fumigated with an insecticide at least once a week, on non-working days.

**Preparation of the Operating Room**

The operating room should be cleaned and set up before the client enters.

- Decontamination solution (0.5% chlorine), freshly made on the day of the surgery, should be placed in plastic containers in the operating room.
- Appropriately processed and sterilized instrument kits should be opened and arranged on the instrument table by the surgical assistant, who should be scrubbed, gowned and gloved.
- Supplies and drugs needed for the surgery should be readily and handily available.
- Equipment and drugs for emergency management should be readily and handily available.

**Traffic Flow**

The purpose of controlling the number and activity of people in and around the operating room is to minimize the level of microbial contamination. Limiting the traffic flow in the operating room and other procedure rooms is an efficient way to maintain a state of cleanliness within the O.R. The surgical suite should be arranged in such a way as to facilitate orderly flow of clients and staff.

The number of people and movement should be kept to a minimum, since the number of microorganisms in an area tends to be related to the number of people present and their activity. Only persons who are assisting with the procedures should be permitted in the room. Staff should never use the operating room as a thoroughfare. Keeping the door of the operating room closed at all times and keeping it locked when the room is not in use helps minimize traffic flow.

**Cleaning the Operating Room**

On the morning of each day that the operating theater is to be in use, the floor should be cleaned with a damp (water only) mop and counters and tabletops wiped with a damp rag (water only). After each case, the operating table, instrument stands, and other potentially contaminated areas, such as light handles and counter tops, should be wiped down with a 0.5% chlorine solution. This
C. Procedure should be carried out at the end of the day with a cleaning solution that contains both a disinfectant (chlorine) and a detergent (soap).

The operating theater should be thoroughly cleaned at least once a week. This should include scrubbing the room, including walls, windows, lights, floors, and equipment, with a recommended disinfecting solution. Washing should be done from top to bottom, so that debris, which falls on the floor, will be cleaned up last.

**ESTABLISHING AND MAINTAINING A STERILE FIELD**

A sterile field around the incision is established by applying antiseptic solutions to the abdominal area and placing drapes around the surgical field. The sterile field includes all sterile drapes, the front of the sterile gowns worn by the surgical team (from waist to neck, and from fingertips to elbow, and the instrument tray. Maintenance of the sterile field is the responsibility of the entire surgical team (scrubbed and unscrubbed) and consists of ensuring that only sterile items come into contact with the sterile field and that any contamination is immediately rectified.

Although any member of the team can perform skin preparation, draping can be performed only by those who are scrubbed, gowned, and gloved. The assistant and surgeon do draping together. The use of a single, fenestrated drape facilitates establishment of a sterile field.

To maintain a sterile field:

- Allow only sterile items and personnel within the sterile field.
- Work only within the limits of the sterile field.
- Do not contaminate items when opening, dispensing, or transferring them.
- Consider any sterile item that has been penetrated (cut, wet, or torn) to be nonsterile.
- Never set up a sterile field near a door or an open window.
- When in doubt as to whether an item is still sterile, consider it to be contaminated.
GOOD SURGICAL TECHNIQUE

Meticulous attention to bleeding and gentle handling of tissue during surgery can help reduce the risk of infection. Post-procedure infections are most likely to occur when tissues have been damaged through rough handling or excessive manipulation during surgery or when there is excessive bleeding.

WASTE DISPOSAL

Contaminated wastes are a potential source of infection for staff as well as for the local community if the wastes are not disposed of properly. A health care facility generates different kinds of wastes.

Kinds of Waste

The World Health Organization classified the waste generated from a health care facility into two: the general waste, and the hazardous medical wastes.

1. General waste

These are non-hazardous wastes that pose no risk of injury or infections. These are similar in nature to household trash. Examples are: paper, boxes, packaging materials, bottles, plastic containers, and food-related trash.

2. Hazardous medical waste

These are the 10 – 25% fraction of healthcare wastes that are classified into the following waste groups.

- Infectious – all wastes that are susceptible to contain pathogens (or their toxins) in sufficient concentration to cause diseases to a potential host. e.g. excreta, tissue swabs, blood bags, dressings, etc.
- Pathological – consist of human tissues or fluids e.g. body parts, blood, blood products and other body fluids, placentas, and product of conception, materials containing fresh or dried blood or body fluids such as bandages, and surgical sponges.
- Pharmaceutical - are expired, unused, and contaminated pharmaceutical products, drugs, vaccines that are no longer needed. It also includes discarded items used in handling pharmaceuticals such as bottles, or boxes with residue, gloves, masks, connecting tubings, and drug vials.
- Chemicals - are the discarded solid, liquid, and gaseous chemicals used in cleaning, housekeeping, and disinfecting procedures.
- Sharps - items that could cause cuts, puncture wounds, including hypodermic and suture needles, scalpel blades, blood tubes, infusion sets, and other glass items that have been in contact with potentially infectious materials (such as glass slides and coverslips)
- Pressurized containers – consist of full or emptied containers or aerosol cans with pressurized liquid gas or powdered materials
- Highly infectious – consists of microbial cultures and stocks of highly infectious agents. It includes body fluids of patients with highly infectious diseases.
- Genotoxic - waste containing genotoxic properties e.g. drugs used in cancer therapy
- Radioactive - consist of liquids, gas, and solids contaminated with radionuclides whose radiations have genotoxic effects e.g. radiation from X-rays
- Waste with high content of heavy metals – e.g. cadmium or mercury from thermometers or manometers.

Since the disposal of medical waste is frequently a problem, it is useful to develop a medical waste management plan and a staff be assigned the responsibility of waste disposal.

**The Four Steps of Hazardous (Medical) Waste Management**

The management of waste must be consistent from the point of generation to the point of final disposal. The path between these two points can be segmented into four steps.

1. **Sorting or segregation and containerization**

   Only a small percentage of the waste generated by a healthcare facility is medical waste that must be specially handled to reduce the risk of infections or injury. Therefore, sorting the waste at the point at which it is generated can greatly reduce the amount that needs special handling.

   The correct segregation/sorting of waste at the point of generation relies on a clear identification of the different categories of waste and the separate disposal of the waste in accordance with the categorization chosen. To encourage segregation at source, reusable containers with plastic liners of correct size and thickness are placed as close to the point of generation as possible. They should be properly color coded.

   - Black trash bag: General-Non-Infectious-Dry
   - Green trash bag: General-Non-infectious-Wet
   - Yellow trash bag: Infectious-Pathological
   - Sharp container: Sharps

   Needles and other sharps pose the greatest risk of injury, and should be disposed of in special sharps containers such as heavy cardboard boxes, tin cans with lid and plastic bottles.

2. **Handling**

   Handle medical waste as little as possible before disposal. When waste containers are ¾ full, the liners are closed with plastic strings and are placed in larger containers at the interim storage areas. Always wear heavy utility gloves when handling medical waste. Always wash your hands after handling wastes and after removing your gloves.

3. **Interim storage**

   In order to avoid both the accumulation and decomposition of waste, it must be collected on a regular daily basis. Waste should never be stored in the facility for more than one or two days.

   If it is necessary to store medical waste on-site before final disposal, waste should be placed in an area that is minimally accessible to clinic staff, clients and visitors.

4. **Final disposal**

   **General wastes**, similar to household waste, can be collected by the regular municipal garbage collector and transported into the final dump sites.
Solid Medical Waste

**Building and using a waste-burial pit**

1. Choose an appropriate site that is at least 50 meters away from any water source to prevent contamination of water source. The site should have proper drainage, be located downhill from the wells, be free of standing water, and be in an area that does not flood. The site should not be located on land that will be used for agriculture or development.

2. Dig a pit 1 to 2 meters wide and 2 to 5 meters deep. The bottom of the pit should be 1.8 meters above water table.

3. Fence in the area to keep out animals, scavengers, and children.

4. Keep waste covered. Every time waste is added to the pit, cover it with a 10 to 30cm layer of soil.

5. Seal the pit when the level of waste reaches 30 to 50 cm of the surface of the ground. Fill the pit with dirt, seal it with concrete and dig another pit.

There are three options for the disposal of solid medical waste: burning waste, burying waste, and transporting waste to an off-site disposal site.

In our country burning waste is not applicable because of the Clean Air Act. So the remaining options are:

- burying, that is if there is a space at the back of one’s facility to dig a pit;
- and transporting waste to an off-site disposal site. This is done by the waste collector of hospital medical wastes.

**Liquid medical waste**

The following are the procedures when disposing liquid medical wastes:

1. Carefully pour liquid waste down a sink, drain or flushable toilet.

2. Before pouring liquid waste down a sink, drain, or toilet, consider where the drain empties. It is hazardous for liquid waste to run through open gutters that empty onto the grounds of the facility.

3. Rinse the sink, drain, or toilet thoroughly with water to remove residue waste – again avoid splashing. Clean these areas with a disinfectant cleaning solution at the end of the day or more frequently if heavily soiled.

4. Decontaminate the container that held the liquid waste by filling it with 0.5% chlorine solution for 10 minutes before washing.

5. Wash your gloved hands after handling liquid waste before removing gloves.

**DISPOSAL OF NEEDLES AND OTHER SHARP OBJECTS**

To avoid accidental needle sticks, staff should not bend, break, or clip needles prior to disposal. **Needles should not be recapped routinely**, since many needle-stick injuries are self-inflicted
during cap replacement. The assembled needle and syringe should be discarded in a puncture-proof container. If recapping is necessary, staff should use the one-handed method:

- First, place the cap on a hard, flat surface, and then remove hand.
- Second, with one hand, hold the syringe and use the needle to “scoop up” the cap.
- Finally, when the cap covers the needle completely, use the other hand to carefully secure the cap on the needle. Alternately, the cap can be held with a clamp while placing it back over the needle.

Sharps should be disposed of in a puncture-resistant lidded container, made of either metal or heavy, rigid plastic. Sturdy and empty plastic bottles from antiseptic or other solutions can be used for this purpose as well as empty glass intravenous fluid bottle; however, with the latter there is a risk of breakage. The container should be close to the area where it will be used so that staffs do not have to carry sharp items a long distance before disposal. This increases the risk of injury.

The container with sharp objects should be tightly capped, plugged, or taped closed when it is three-quarters full. It should be disposed of by burying. Needles and other sharp objects may not be destroyed by burning, and may later cause injuries that can lead to serious infection. However, incineration or burning in a container does make those items less scavengable and will destroy HIV and HBV.

The table below provides a list of available antiseptics with their efficacy and potential uses.

Savlon which contains chlorhexidine, is not listed because the concentration of chlorhexidine varies from country to country, from as little as 1% to 4%.

Session 5

THE SURGICAL TEAM

OVERVIEW

Minilaparotomy performed under local anesthesia requires a team effort—a group of providers working in coordination to perform a refined surgical technique while ensuring safety, efficacy, and client comfort. As a group, they should make sure to implement the tasks needed to conduct surgery efficiently.

This session provides service providers with the knowledge on the responsibilities of each member of the surgical team to perform BTL/MLLA efficiently with consideration of the clients’ comfort and safety.

LEARNING OBJECTIVES

At the end of the session, the participants will be able to:

1. Explain what the “surgical team” is.
2. Discuss the components of a surgical team and the responsibilities of each member of the team.
3. Explain the tasks of the members of the surgical team before, during, and after minilap under local anesthesia.

PREPARATION

- PowerPoint slides on “The Surgical Team”
- Computer and LCD
- Whiteboard and appropriate marker
- Tapes

TIME ALLOTMENT

1 hour

### Responsibilities of Surgical Team Members

<table>
<thead>
<tr>
<th>Role</th>
<th>Responsibilities</th>
</tr>
</thead>
</table>
| **Surgeon**           | Responsible for the surgical team’s overall performance by supervising the tasks for female sterilization:  
  - Informed decision making  
  - Completion of informed consent form  
  - Preoperative assessment  
  - Correct implementation of infection prevention measures  
  - Appropriate and continuous client monitoring  
  - Adequate recovery monitoring  
  - Provision of post-operative instructions  
  - Confirmation that the clinic is prepared for emergencies  
  - Performs the surgery |
| **Surgical assistant**| Assist the surgeon by optimizing exposure of the uterus and fallopian tubes  
  - Preparation of sterile instruments and supplies for surgery |
| **Circulating nurse** | Prepares the operating room for the surgery  
  - Ensures availability of supplies and instruments in the operating room  
  - Provides sedative and analgesic drugs  
  - Observes for early signs of complications  
  - Ensures that the client is comfortable during the procedure  
  - Alerts the surgeon for signs of complications |
| **Client monitor**     | Prepares clients for the surgery  
  - Provides post-operative care to clients  
  - Observes signs of immediate post-operative complications  
  - Refers untoward events during recovery to the surgeon |
Tell participants that:

- The surgeon, being the leader of the surgical team, must know the responsibilities of each member of the team.

- This exercise will make the surgeon realize these responsibilities.

Divide participants into 3 groups.

Assign the groups as follows:

- Group 1: Surgeon
- Group 2: Surgical Assistant
- Group 3: Circulating Nurse
- Group 4: Client Monitor

Each group discusses and enumerates the task of the team member assigned to them before, during, and after surgery.

After 10 minutes, each group reporter presents the group’s output in plenary.

Conclusion

Conclude the session by eliciting requests for clarifications from the participants.

Respond, as needed.
NARRATIVE

To perform an effective surgical procedure that ensures client safety, and client comfort, the surgical team should consist of at least four people: a surgeon, a surgical assistant, circulating nurse and a client monitor.

Each member of the surgical team has very distinct responsibilities:

- The **surgeon** ensures that the client is fit for the procedure, performs the surgery and is responsible for the surgical team’s overall performance.

- The **surgical assistant** assists the surgeon by optimizing exposure of the uterus and fallopian tubes, cutting sutures, and anticipating the surgeon’s needs.

- The **circulating nurse** is responsible for:
  - Preparing the operating room before the client enters together with the surgical assistant
  - Ensuring that needed supplies and instruments are available in the operating room
  - Providing sedative and/or analgesic drugs prior to surgery and checking effectiveness of these
  - Monitoring the client’s vital signs
  - Communicating with the client
  - Observing early signs of complications
  - Immediately alerting the surgeon for signs of complications
  - Handling any additional supplies that the surgeon may request during the surgery

- The **client monitor** is responsible for providing post-operative care to clients. This includes:
  - Monitoring vital signs every 15 minutes until these are stable post-operatively
  - Observing signs of post-operative complications (e.g., lowering of blood pressure with increasing pulse rate, excessive bleeding from operative site, pallor, difficulty of breathing, severe abdominal pain, inability to urinate)
  - Referring to the surgeon any untoward events during recovery
  - Encouraging clients to ambulate once fully awake
  - Ensuring that clients can tolerate oral intake post-operatively

As team leader, the surgeon is ultimately responsible for supervising the steps needed for BTL, such as:

- Informed decision making
- Completion of the informed consent form
- Preoperative assessment
• Correct implementation of infection prevention procedures
• Appropriate and continuous client monitoring
• Choice and appropriate management of the anesthesia regimen
• Adequate recovery monitoring
• Provision of postoperative instructions
• Confirmation that the clinic is equipped and ready to manage any emergency

The surgeon should also have a leadership role in analyzing practices of the team that need to be changed to improve the quality of care. This can be done through regular review with the team of all records of complications, surgical difficulties, and problems identified at follow-up visits.

The table below summarizes the tasks of the members of the surgical team.
### Tasks of the Members of the Surgical Team: Surgeon, Surgical Assistant, Circulating Staff, Client Monitor

Session 6

PREPARATION FOR SURGERY

OVERVIEW
Instituting measures to adequately prepare clients for BTL/MLLA will foster client satisfaction, eliminate future regrets and prevent complications. Preparation for surgery includes preoperative assessment and screening, provision of preoperative instructions, and review with the client of what to expect during the procedure.

This session provides the necessary information on the process for preparing the client for BTL/MLLA.

LEARNING OBJECTIVES
At the end of the session, the participants will be able to:
1. Discuss the components of client preparation for surgery.
   • Pre-operative assessment screening
   • Pre-operative and post-operative instructions
   • Review of what to expect during the procedure
2. Identify client conditions suitable for female sterilization using the WHO-MEC.
3. Explain how to manage clients who are not eligible for BTL by BTL/MLLA.

PREPARATION
• PowerPoint slides on “Preparation for Surgery”
• Computer and LCD
• Whiteboard and appropriate marker

TIME ALLOTMENT
1 hour

<tbody>
<tr>
<td>Discuss “Pre-Operative Assessment” using the appropriate PowerPoint slides below.</td>
</tr>
</tbody>
</table>
Importance

- To identify conditions that will affect the procedure and anesthesia regimen
- To determine client’s fitness for surgery
- To ensure that the client’s decision is voluntary and informed
- To provide an opportunity for overall health screening

Who Is Responsible

- Trained staff conducts preliminary screening by:
  - Performing medical history using FP Form 1
  - Screening based on WHO medical eligibility criteria
  - Referring clients with abnormalities to the doctor
- Doctor/surgeon makes the final decision to offer or deny ML-LA to the client

Components

- Medical history
- Physical examination, including pelvic examination
- Laboratory tests, as needed

Tell participants that:

- The WHO has recommended procedures necessary for assessing clients’ suitability for using contraceptive methods.
- Performing other procedures and requesting for additional tests, other than recommended, may cause barriers to using these methods.
- Additional tests performed may be for the reason of investigating other medical conditions but not for determining the client’s suitability for
Bilateral Tubal Ligation by Minilaparotomy under Local Anesthesia

### Medical History

- **History of past medical conditions related to each organ system**
- **Reproductive health history**
  - Number of pregnancies
  - Number of living children and their age
  - Last pregnancy outcome
  - Last normal menstrual period
  - Contraceptive history
  - Risk for STIs
  - History of violence
- **History of previous surgeries, anesthesia, allergies, and medications**
- **Present illness, if any**

### Medical History

- **For postpartum clients:**
  - History of complications during pregnancy and delivery which may cause complications
  - Assess well-being of the baby
- **For postabortion clients:**
  - History of conditions which are potential risks for complications (e.g., infection, uterine perforation, or significant blood loss)

---

**Provider Checklist for Reproductive Health Services: How to Be Reasonably Sure a Client Is Not Pregnant**

<table>
<thead>
<tr>
<th>No.</th>
<th>Yes</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Did your last menses occur in months ago and are there any signs that they are due in the expected period?</td>
<td></td>
</tr>
<tr>
<td>2. Has there been a history of regular menstrual cycles over last menstrual period?</td>
<td></td>
</tr>
<tr>
<td>3. Have you noticed any unusual symptoms since last menstrual period?</td>
<td></td>
</tr>
</tbody>
</table>

- The client answered NO to all of the questions.
- Pregnancy cannot be ruled out.
- The client answered YES to at least one question.
- The client is free of signs of complicity of pregnancy.
- The client should not menstruate for at least one month.

Possibility of pregnancy must be ruled out.

Discuss “Medical History” as presented on the slides with additional insights from participants.
Physical Examination

- Taking and documentation of vital signs
- Auscultation of the heart and lungs
- Inspection and palpation of the abdomen
- Pelvic examination

Laboratory Tests

When minilaparotomy is performed under local anesthesia, it is not necessary to do routine laboratory testing. Diagnostic laboratory tests are necessary only when warranted by the client’s history or results of the physical examination.

Describe the “WHO-MEC” as presented on the slide.
Ask participants at random to state the WHO-MEC recommendation for the following conditions:

- Pregnancy
- Young age
- Nulliparous
- Mild pre-eclampsia
- Severe pre-eclampsia
- Obesity
- Hypertension
- Vaginitis
- Current purulent cervicitis
- Headache
- Varicose veins
- Depressive disorders
- Unexplained vaginal bleeding
- Diabetes

State the optimal schedule for performing BTL/MLA as presented on the slides.

**Scheduling**

- **Postpartum clients**
  - Immediate postpartum up to 6 days after delivery
- **Postabortion clients**
  - Within first 6 hours and up to 7 days after evacuation of the uterus
- **Interval clients**
  - From 42 days postpartum
  - At any time provided the service provider is reasonably certain that the woman is not pregnant
Scheduling

Remember….

If client’s present condition disqualifies her from having the procedure at the present time, offer a reliable method of contraception to protect her from pregnancy until the surgery can be performed.

Key Points

• There is no medical condition that would absolutely restrict a woman’s eligibility for BTL.
• However, not all women can undergo BTL by MLLA (some with Caution and all with Special categories of conditions). The following options are available for such clients:
  o BTL performed in facilities capable of providing spinal and general anesthesia
  o Use of long-term methods (i.e., IUD, implant, injectable)

Tell participants that:

• Clients requesting for BTL have the strong need/desire to stop their fertility.
• It is the FP service provider’s responsibility to help clients satisfy their reproductive need.
• The FP service provider must discuss with the client her options if she is not eligible for BTL/MLLA.

Emphasize the “Key Points” on clients’ options, should they have conditions which are categorized as C-Caution or S-Special.

Pre-Operative Instructions

Tell participants that:

• Adequate preparation of clients for BTL/MLLA diminishes client discomfort and is an important factor for success of the procedure.
**Importance**

- Prepares the client for the procedure thereby ensuring safety of the procedure
- An opportunity for the client to ask questions and be clarified
- An opportunity to reassure the client and check on her understanding of the instructions given
- Instructs the client on what to do after the procedure

**What to Do Before Surgery**

- Not to eat solid food for 6 hours before surgery but may take clear fluids up to 2 hours before surgery
- Bathe, clean the genital area and operative site, and remove jewelry, make-up, and nail polish on the day of surgery
- Have a responsible adult to accompany her

**Postoperative Instructions**

- Rest for the remainder of the day. Resume normal activities after 2 or 3 days.
- Avoid intercourse until comfortable.
- For relief of pain or discomfort, take simple analgesics at intervals of 4 to 6 hours.
- Keep the wound clean and dry.
- The stitches will dissolve and do not have to be removed.
- Keep in mind where to go for urgent care for warning signs (i.e., fever, increasing pain in the abdomen, bleeding from the incision site, or suspected pregnancy.)

Sample Preoperative and Postoperative Instructions to Clients (Oral and Written)

What You Should Know about Your Sterilization Operation

This leaflet contains important information that you need to know. It tells you how to prepare for your sterilization operation and how to take care of yourself afterwards.

Remember—sterilization is a surgical procedure. It is meant to be permanent. After sterilization, you will no longer be able to get pregnant. If you have any questions or doubts, talk to the clinic staff. We are here to help you.

Before going to the clinic:
1. Do not eat any solid food for at least six hours before surgery, but you may drink clear fluids up to two hours before the operation. You will be able to eat and drink after the operation.
2. Have a bath. Carefully wash your belly button, belly, genital area using soap.
3. Wear clean, loose clothing.
4. Arrange for a family member or friend to come to the clinic to help you home after the operation.

Bilateral Tubal Ligation by Minilaparotomy under Local Anesthesia

Ask participants:

- Why is reviewing the BTL/MLLA procedure with the client in a language that she understands important?

Acknowledge response of the participants.

State the “Importance” of reviewing the procedure with the client as presented on the slide.

Add participants’ responses that are not covered by the points presented on the slide.

Discuss what is being told to clients about the procedure as presented on the slides.

Encourage participants to supplement the presentation.

---

**Importance**

- Informs and reassures the client as she knows what to expect during the procedure
- Key to the success of local anesthesia and decreases the need for sedation and analgesia as it reduces apprehension and anxiety

**What to tell the client…**

- The doctor will perform a pelvic examination before starting the surgery
- A uterine elevator will be inserted through the vagina into the uterus which may cause cramping
- She will be given a sedative which will make her sleepy during the operation.
- Her belly will be washed with soapy liquid

---

**Review of the Procedure**

---

---
**What to tell the client…**

- She will be covered with a drape so she will not be able to see the operation but can ask questions whenever she wishes.
- The table will be tilted down for part of the time so that her head is lower than her feet.
- She will feel a needlestick in her belly when the doctor injects the anesthetic. This will make the area around the injection numb.

**What to tell the client…**

- She will probably feel some tugging, pulling, and slight cramping.
- The procedure lasts for around 30 minutes.
- After the procedure, a staff will help her get off the operating table and walk her to the recovery area.
- She will stay in the recovery room about 2 hours—until she feels steady enough to walk and staff have checked her.

**Conclusion**

Ask participants at random:

- What have you learned during the session?

Compare the responses to the objectives of the session.
The preparation for surgery includes preoperative assessment and screening, preoperative instructions, and review of what to expect during the procedure. Preoperative assessment is essential in the provision of MLLA services to determine the client’s fitness for surgery, identify conditions that will affect the procedure and anesthesia regimen and to ensure that the client’s decision is voluntary and informed. The preoperative assessment can also provide an opportunity for overall health screening. This is particularly important in countries where many people rarely visit a health facility or where health services are inadequate. Clients should also be screened for sexually transmitted diseases (STDs) and treated or referred for treatment.

**PRE-OPERATIVE ASSESSMENT**

The pre-operative assessment should be conducted before surgery is scheduled to screen for conditions that warrant caution, delay, or special/refer consideration. The WHO Medical Eligibility Criteria (WHO MEC) provides recommendations based on the latest clinical evidence available on the safety of the methods for people with certain health conditions.

**WHO IS RESPONSIBLE FOR PREOPERATIVE ASSESSMENT?**

Any health care provider trained in taking a complete medical history and in performing a complete physical examination, including a pelvic examination, can perform the preoperative assessment. This person should be qualified to recognize and appropriately identify conditions that might lead to surgical complications. This person must be able to use the WHO Medical Eligibility Criteria to avoid complications without being overly cautious to pose a barrier in the provision of the service.

**COMPONENTS OF THE PREOPERATIVE ASSESSMENT**

The table below provides the WHO recommendation on the applicability of various procedures and tests for using contraceptive methods, including BTL.

Adapted from: WHO Medical Eligibility Criteria for Contraceptive Use, Third Edition, 2004

* Class A = essential and mandatory in all circumstances for safe and effective use of the contraceptive method.

Class B = contributes substantially to safe and effective use, but implementation may be considered within the public health and/or service context. The risk of not performing an examination or test should be balanced against the benefits of making the contraceptive methods available.

Class C = does not contribute substantially to safe and effective use of the contraceptive method.

Notes

The Medical Eligibility Criteria for Contraceptive Use, Third Edition, 2004 states that:

1. If a woman has a very high individual likelihood of exposure to gonorrhea or chlamydial infection, she should generally not have an IUD inserted unless other methods are not available or not acceptable. If she has current purulent cervicitis or gonorrhea or chlamydial infection, then she should not have an IUD inserted until these conditions are resolved and she is otherwise medically eligible.

2. Women at high risk of HIV infection should not use spermicides containing nonoxynol-9. Using diaphragms and cervical caps with nonoxynol-9 is not usually recommended for women at high risk of HIV infection unless other more appropriate methods are not available or not acceptable. The contraceptive effectiveness of diaphragms and cervical caps without nonoxynol-9 has been insufficiently studied and should be assumed to be less than that of diaphragms and cervical caps with nonoxynol-9.

3. It is desirable to have blood pressure measurements taken before initiation of COCs, CICs, POPs, POIs, and implants. However, blood pressure measurements are unavailable in many settings, pregnancy morbidity and mortality risks are high, and hormonal methods among the few methods widely available. In such settings, women should not be denied the use of hormonal methods simply because their blood pressure cannot be measured.

4. For procedures performed using local anesthesia with ephedrine.
In the preoperative assessment, the provider takes a complete medical history and conducts a physical examination. Laboratory tests are performed only to confirm abnormal findings from the medical history and/or physical examination.

The **medical history** that is taken must be complete, whether or not questions are specifically related to the surgical procedure. The Family Planning Service Record (FP Form 1) is the standard form of the Department of Health for recording the health condition of family planning clients. As contained in the FP Form 1, the medical history includes a history of past medical conditions (related to each organ system), a reproductive health history (e.g., number of pregnancies, number of living children and their age, last pregnancy outcome, and last normal menstrual period, contraceptive history, and history and risk for STIs) and the history of any previous surgeries, allergies, and medications. Clients should be asked about any current illnesses or any symptoms that could add risk to the procedure or that could warrant a postponement.

The **physical examination** should include taking and documenting vital signs and conducting a cardiopulmonary, abdominal, and gynecological examination. For clients who will undergo interval or post-abortion minilaparotomy, the physical examination should include a bimanual pelvic examination to determine the position, flexion, mobility, size, shape and condition of the uterus. The mobility of a retroverted or retroflexed uterus should be carefully assessed. Although the surgeon may be able to gain access to the tubes by means of the uterine elevator, a uterus that is retroverted and retroflexed and fixed will not be elevated easily and may require a different surgical approach through a larger incision or more anesthesia.
Bimanual pelvic examination of a retroverted or retroflexed uterus

In addition to the usual history-taking, the presence of any complicating conditions related to the delivery (e.g., potential infection, excessive blood loss during delivery or immediate postpartum, and complications associated with pregnancy-induced high blood pressure) should be assessed. The well-being of the baby should also be assured. An abdominal examination is important for assessing the size and relative location of the uterine fundus. A bimanual examination need not be performed.

For post-abortion clients, the provider must be sure that there is no infection, uterine perforation, or significant blood loss. Uterine size should also be assessed, as this will influence the surgical approach selected.

Diagnostic laboratory tests such as hematocrit or hemoglobin are necessary only when warranted by the client's history or the results of the physical examination.

The possibility of pregnancy must also be ruled out, but there is no need to perform a pregnancy test. Instead, the provider may use the algorithm below on “How to Be Reasonably Sure a Client Is Not Pregnant”.

---

Bilateral Tubal Ligation by Minilaporotomy under Local Anesthesia
MEDICAL ELIGIBILITY CRITERIA FOR BTL

There is no medical reason that would absolutely restrict a woman’s eligibility for BTL. However, not all women are eligible for BTL/MLLA. Some conditions and circumstances, which should be identified during the preoperative assessment, may indicate the need to take certain additional precautions. The WHO guidelines for screening clients for BTL with recommendations on their eligibility given certain conditions are given below.

For clients who are not eligible for BTL/MLLA, the following options are offered during counseling:

- BTL under spinal or general anesthesia in facilities capable of providing services. The client may need to be referred to these facilities.
- Choosing long-term temporary FP methods (i.e., IUD, injectables, implants)
Surgical Sterilization Procedures

Considering the irreversibility or permanence of sterilization procedures, special care must be taken to ensure that the client has made a voluntary informed choice to have the procedure. Particular attention must be given in the case of young people, nulliparous women, and male partners who have not yet been fathers, and in clients with mental health problems, including depressive conditions. All women should be counseled about the permanence of sterilization and the availability of alternative, long-term, highly effective methods; this is of extra concern for young people. The national laws and existing norms for the delivery of sterilization procedures must be considered in the decision-making process.

There is no medical condition that would absolutely restrict a person’s eligibility for sterilization. Some conditions and circumstances indicate that certain precautions should be taken.

The classification of conditions into the different categories is based on an in-depth review of the epidemiological and clinical evidence relevant to medical eligibility. The programmatic implications of these updated medical criteria are still to be addressed, taking into account the various levels of service delivery. However, for the particular case of sterilization procedures, the following category definitions were developed.

Definitions

A  Accept: There is no medical reason to deny sterilization to a person with this condition.

C  Caution: The procedure is normally conducted in a routine setting, but with extra preparation and precautions.

D  Delay: The procedure is delayed until the condition is evaluated and/or corrected. Alternative temporary methods of contraception should be provided.

S  Special: The procedure should be undertaken in a setting with an experienced surgeon and staff, equipment needed to provide general anesthesia, and other back-up medical support. For these conditions, the capacity to decide on the most appropriate procedure and anesthesia regimen is also needed. Alternative temporary methods of contraception should be provided, if referral is required or if there is otherwise any delay.
Sterilization does not protect against sexually transmitted infections (STIs) or HIV; if there is risk for STIs or HIV (including during the postpartum period), the correct and consistent use of condoms is recommended, either alone or with another contraceptive method. Male latex condoms are proven to protect against STIs and HIV.

The latest WHO MEC for Female Sterilization is provided in Annex B. For easy reference, a summary of conditions that would warrant “delay” or “special” consideration of BTL/MLLA is provided in the table below.
Conditions warranting either delay of surgery or observation of special considerations before surgery is performed

CLIENT PREPARATION

Scheduling

After being counseled and undergoing pre-operative assessment, clients who will undergo BTL should be scheduled for surgery. Scheduling includes:

• setting a time
• providing alternative contraception, if needed
• providing preoperative and postoperative instructions

Setting a time

For the interval client, BTL can be performed at any time the provider can be reasonably sure that the woman is not pregnant.

For postpartum clients, the time for surgery is set usually within 48 hours up to 7 days of delivery.

Post-abortion clients can undergo the procedure within the first 6 hours up to 7 days after uterine evacuation.

Providing temporary contraception

If pregnancy cannot be ruled out, if any condition requires a delay in performing the surgery, and if the client is not already using a reliable method of contraception, the client should be offered a reliable method of contraception so she is protected from pregnancy until her surgery can be performed.

Providing preoperative information and instructions

Preoperative information and instructions are important. To inform and reassure the client, these should be given in advance, letting her know what to expect during the procedure. This is the key to the success of local anesthesia and decreases the need for sedation and analgesia. Preoperative information and instructions should be given both verbally and in writing. Using simple terms, the counselor provides the following information:

• The steps of the operation
• The anesthesia regimen to be used, an explanation that some discomfort might occur, and encouragement for the client to ask questions
• That the client should not eat any solid food for at least six hours before surgery, but may take clear fluids up to two hours before surgery.
• The need for interval clients to bathe, clean the genital area and operative site, and remove jewelry, make-up, and nail polish on the day of the surgery.
• The importance of having a responsible adult to take the client home from the facility after the procedure.

In addition, information about what to expect after the surgery should be provided at this time and it should include the following:

• Needed rest, wound care, and when to restart normal activities (including intercourse)
• Warning signs to be aware of, what to do in each case, and where to go in the event those complications arise.
• When and where to go for the follow-up visit

Providing postoperative instructions

After surgery, the information already provided regarding postoperative care should be reiterated and reviewed. These instructions are especially important in helping women recognize warning signs and seek timely care. Clients should receive written instructions just before they leave the facility, with special attention to the following:
• Rest for the remainder of the day. Resume normal activities after two or three days.
• Avoid intercourse until comfortable.
• For relief of pain, take simple analgesics like paracetamol every four hours.
• Keep the wound clean and dry.
• The stitches will dissolve and do not have to be removed.
• Keep in mind where to go for urgent care in case warning signs develop, such as:
  - Fever
  - Persistent and increasing pain in the abdomen
  - Bleeding from the incision site
  - Suspected pregnancy

Below is a sample of a written preoperative and postoperative instruction which can be translated in the dialect.
What You Should Know About Your Sterilization Operation

This leaflet contains important information that you need to know. It tells you how to prepare for your sterilization operation and how to take care of yourself afterwards.

Remember, sterilization is a surgical procedure. It is meant to be permanent. After sterilization, you will no longer be able to get pregnant. If you have any questions or doubts, talk to the clinic staff. We are here to help you.

Before going to the clinic:

1. Do not eat any solid food for at least six hours before surgery; but you may drink clear fluids up to two hours before the operation. You will be able to eat and drink after the operation.
2. Have a bath. Carefully wash your belly button, belly, and genital area using soap.
3. Wear clean, loose clothing.
4. Arrange for a family member or friend to come to the clinic to help you home after the operation.

When you return home:

1. Rest for one or two days at home. You will probably be able to resume most of your normal activities within three to five days. Avoid heavy work or lifting for one week. This will help the wound heal.
2. Do not let the bandage get wet for one or two days.
3. Take the medicine provided by the clinic.
4. You may have sex as soon as it is comfortable for you. This is usually about one week after the operation.
5. Avoid pulling, scratching, or irritating the wound.
6. It is important for you to know what is normal following your surgery. There will probably be some pain and swelling around the wound. This is normal and should not worry you.
7. Return to the clinic and notify the doctor or health worker if you have any of the following, or if you notice any unusual body changes:
   - Fever within one week of the operation
   - A pain in your belly that does not go away or that becomes worse
   - Bleeding or pus coming from the wound
   - Signs that you may be pregnant - a missed period, stomach pains, or dark or spotty bleeding between periods (Watch for these signs at any time after the operation. They may mean that the operation has failed and that you may be pregnant.)

For any of these problems, you should telephone or go to the following location for medical care without delay:

(Add appropriate address)

Telephone Number:_____________

Session 7
THE LOCAL ANESTHESIA REGIMEN

OVERVIEW

Minimizing psychological and emotional distress and trauma to the client, and freeing her from pain and discomfort increases acceptance of BTL/MLLA. While anesthesia regimens may vary depending on local practices, every minilaparotomy program should adopt and implement simple, standard analgesia and anesthesia regimens in order to ensure quality control. Local anesthesia with analgesia and/or light sedation is both suitable and safe for minilaparotomy.

This session provides trainees with the knowledge on the local anesthesia regimen appropriate for MLLA.

LEARNING OBJECTIVES

At the end of the session, the participants will be able to:

1. State the goals of anesthesia and analgesia.
2. Explain the choice of local anesthesia with systemic analgesia for BTL/MLLA.
3. Discuss the preparation of the client for local anesthesia.
4. Describe the drugs used for local anesthesia with systemic analgesia.
5. Discuss the guidelines for using local anesthesia.
6. Enumerate the steps of infiltrating local anesthesia relevant to BTL/MLLA.
7. Explain how clients on local anesthesia with systemic analgesia are monitored.

PREPARATION

- PowerPoint slides on “The Local Anesthesia Regimen”
- Computer and LCD
- Whiteboard and appropriate marker

TIME ALLOTMENT

1 hour 30 minutes

Jacobstein R., Cordero C., and Ahlborg J. Pain Management for Female Sterilization by Minilaparotomy. ACQUIRE Clinical Update. USAID. August 2007

**CONTENT**

**TEACHING-LEARNING PROCESS**

Introduce the session by providing an “Overview” of the session.

---

**Local Anesthesia Regimen**

---

**Objectives**

- State the goals of anesthesia and analgesia
- Explain the choice of local anesthesia with systemic analgesia for ML-LA
- Discuss the preparation of the client for local anesthesia
- Describe the drugs used for local anesthesia with systemic analgesia
- Discuss the guidelines for using local anesthesia with systemic analgesia relevant to ML-LA
- Enumerate the steps of infiltrating local anesthesia relevant to ML-LA
- Explain how clients on local anesthesia with systemic analgesia are monitored

---

State the objectives of the session as presented on the slide.

---

**Goals of Anesthesia and Analgesia**

- To minimize psychological and emotional distress and trauma to the client
- Free the client of pain and discomfort.

---

Ask participants:

- Why do we use analgesia and anesthesia for operative clients?

Call participants at random to respond to the question.

Acknowledge participant responses.

Flash the slide on the “Goals of Anesthesia and Analgesia” and relate this to the responses of participants.
Choosing the Regimen

Factors to consider:
- Technical capability of the surgeon, the one who administers and the one who monitors the client during surgery and recovery
- Drugs chosen must be safe, affordable, readily available and procurable.
- Duration of the anesthesia effect must be compatible with the duration of the surgical procedure—effects must not last significantly longer than the procedure

State the factors to consider when choosing the anesthesia regimen as presented on the slide.

Why Local Anesthesia

Advantages:
- It is a simple, safe regimen that is easy to adopt in most settings
- Special equipment is not needed
- Presence of an anesthesiologist is not required
- Client is awake, responsive, and cooperative

Local anesthesia with systemic analgesia found to be well suited for outpatient settings

Provide participants the reasons for the program's choice of using local anesthesia for BTL.

Elicit ideas from participants.

Preparation of the Client

Emotional Readiness
- Requires that the client is calm and relaxed during the procedure
  - Client should be made aware of what she will see, hear, and feel, and how long she will be in the operating and recovery room.
  - Staff should reassure the client and answer any questions.
  - Talking to the client during the procedure

State the ways of preparing the client for local anesthesia as presented on the slide.

Pharmacology of Drugs

Tell participants that the following slides will present the pharmacology of drugs commonly used for analgesia and anesthesia for BTL/MLLA.

Describe the drugs as presented on the slides.
### Lidocaine Hydrochloride (XYLOCAINE)

- **Action**: Prevents generation and transmission of impulses along nerve fibers and nerve endings.
- **Dosage**: 5 mg/kg
- **Adverse Effects**: Seen after accidental intravenous injection
  - Numbness of the tongue and mouth, light-headedness, tinnitus, visual disturbances, slurring of speech
  - Loss of consciousness and convulsions

### Meperidine Hydrochloride (DEMEROL)

- **Action**: Narcotic analgesic for the relief of pain
- **Dosage**: 50 mg IV (initial), 25 mg (additional, if needed); given over a period of 30 seconds
- **Adverse Effects**: Respiratory depression, hypotension, and profound sedation
- **Orthostatic hypotension**
- **Treatment of overdose**: Oxygen inhalation, IVF, vaspressors
  - Naloxone = 0.4 mg. IV, repeat after 2-3 mins as needed for a maximum dose of 2 mg

### Diazepam (VALIUM)

- **Action**: Anticonvulsant, anxiolytic, sedative, muscle-relaxant
- **Dosage**: 10 mg given orally for over 35 kg BW
  - 5-10 mg slow IV at start of procedure (1ml/min)
- **Adverse Effects**: Respiratory depression risk increased when used together with narcotic analgesic
- **Treatment of overdose**: Oxygen inhalation, IVF
  - Naloxone = 0.4 mg. IV, repeat after 2-3 mins as needed for a maximum dose of 2 mg

### Dormicum (MIDAZOLAM)

- **Action**: Short-acting anxiolytic, sedative
- **Dosage**: 0.5-1mg slow IV
- **Adverse Effects**: Respiratory depression and arrest
- **Treatment of overdose**: Oxygen inhalation, IVF
  - Naloxone = 0.4 mg. IV, repeat after 2-3 mins as needed for a maximum dose of 2 mg
Tell participants that:

Though the drugs commonly used for anesthesia and analgesia are safe, some clients may have adverse reactions to any one of these drugs.

As such, clients should be monitored while on these regimen.

Discuss “Monitoring the Client” using the succeeding slides.

### Purpose

- To immediately recognize adverse reactions to drugs
- To immediately institute interventions and prevent complications

### What to monitor...

**Preoperative**
- Take and record vital signs before and after administration of drugs

**Intraoperative**
- Take and record vital signs at least 3x during surgery
- Talk to client

**Postoperative**
- Take and record vital signs every 15 mins. until stable (vital signs at pre-op levels)

Tell participants that:

- Clients’ comfort depends on a painless incision of the abdomen and the dissection of the layers of the abdominal wall.
- This can be achieved by proper infiltration of local anesthetic coupled with gentle dissection of the layers of the abdomen.
Discuss the “Guidelines” for infiltration of local anesthesia using the slides.

**Guidelines**

- **Goal**
  - To achieve an anesthetic block that includes all layers of the abdominal wall

- **Dose**
  - Lidocaine = not to exceed 5 mg/kg
    - 20 cc 1% solution
    - 10 cc 2% solution

Discuss the steps of infiltrating local anesthesia using the slides.

**Guidelines**

- **Infiltration**
  - Infiltrate along the needle track as the needle is withdrawn
  - May need to have additional infiltration while dissecting layers of the abdomen
  - May be dripped on each tube before occlusion
  - Aspirate prior to each infiltration
  - Gently massage the area of infiltration to spread the anesthetic into the tissues
  - Wait 2-3 minutes

**Protocol**

- **Dose:**
  - Lidocaine = not to exceed 5 mg/kg
    - 20 cc 1% solution
    - 10 cc 2% solution

- **2 techniques of infiltration**
  - Diamond-shape
  - Fan-shape

Tell participants that:

- This has the advantage of blocking a larger area.
- This infiltration requires a larger amount of anesthetic like a 20cc of Lidocaine 1%.
- A 1% solution can be prepared by adding an equal amount of distilled water to the 2% Lidocaine solution that is widely available.
Entry of the needle at the incision site

The needle enters the skin in the midline of the incision

Skin infiltration

The needle is then inserted in both lateral directions along the incision line

Infiltration of the fascia

Through the same puncture site, the needle is inserted at a $45^\circ$ angle to the fascia in four directions

Infiltration of the peritoneum

Through the same puncture site, the needle is inserted at a $90^\circ$ angle to the peritoneum

Infiltration of the different layers
**Fan-shape Infiltration**

**Skin infiltration**

The needle is inserted at one end of the chosen skin incision.

**Infiltration of the abdominal layers**

Through the same puncture site, the needle is inserted at a 45° to the fascia. The needle is then withdrawn to the subcutaneous tissue and inserted at 90° straight through the rectus sheath and muscle into the peritoneum.

**Conclusion**

Conclude the session by asking a number of participants to enumerate the steps of infiltration of local anesthesia.

Review the learning objectives of the session; ask questions for each of the objectives to check participants’ learning.
The goals of analgesia and anesthesia are to minimize psychological and emotional distress and trauma to the client, and to free her from pain and discomfort. While anesthesia regimens may vary depending on local practices, every minilaparotomy program should adopt and implement simple, standard analgesia and anesthesia regimens in order to ensure quality control. Local anesthesia with analgesia and/or light sedation is both suitable and safe for minilaparotomy.

When choosing standard regimens, program managers and decision-makers must be certain that the regimens can be administered properly. The regimens must be within the technical capability of the doctor and other program staff who administers anesthesia and sedative drugs, and who monitors the client during surgery and recovery. The drugs chosen for the regimen must be safe, affordable, readily available, and procurable. Their duration of effect must be compatible with the short duration of the surgical procedure—that is, the effects of analgesia and anesthesia must not last significantly longer than the surgical procedure itself. Local anesthesia augmented by systemic analgesia is particularly well suited for outpatient settings.

Local anesthesia produces a local block, and can be augmented with mild systemic analgesia and/or light sedation. The client is awake, responsive, and cooperative. Special equipment is not needed, nor is the presence of an anesthetist required, but if present s/he can administer the sedative and monitor the client. For programs providing minilaparotomy, local anesthesia is the safest regimen. The primary danger in using local anesthesia with sedation is respiratory depression due to excessive narcosis from the sedative medication. Staff must be alert to the action of the drugs and must always use the minimum effective dosage.

To ensure that the client is prepared for the procedure, a doctor, nurse, or counselor explains to her before surgery what to expect in the operating room. For the client to remain calm, it helps if she is aware of what she will see, hear, and feel, and how long she will be in the operating room and the recovery room. Staff should reassure the client and answer any questions. All staff must be especially alert for clients who are extremely anxious about undergoing MLLA. Such clients may find it difficult to relax or remain calm during the procedure and should be offered an alternative anesthesia regimen.

To keep the client calm, operating room staff should speak to the woman throughout the procedure, reassuring her, distracting her, and explaining what is happening. If the client is comfortable and prefers to sleep, the staff should respect this and not disturb her excessively. By observing the woman and how she feels, staff will know if she is experiencing pain and will be able to recognize early signs of complications. Through communication, staff must monitor agitation, difficulty in breathing, or any change in the level of consciousness.

In most facilities a nurse gives the premedication, and the doctor performs infiltration of local anesthesia, but no strict rule governs who will give additional medication if needed. This is a matter program managers must clarify at the outset, so that responsibilities are clearly understood. Much depends on the level of knowledge and the skills of the various members of the surgical team. In the absence of an anesthetist, the doctor must ensure that the person giving medications is skilled in their
administration or is closely supervised. If not, the doctor must decide how to handle emergency situations. In some cases, it may become necessary for the doctor to stop the surgery in order to give emergency treatment, and then re-glove to finish the procedure.

Because the specific title of the person who will be responsible for the administration of all the drugs varies, the word "staff" is used in the following description of drug regimens.

**PREOPERATIVE MEDICATION**

Premedication is used to reduce fear and anxiety. It can provide analgesia, prevent postoperative nausea and vomiting, and induce amnesia.

If premedication is given orally, it should be administered early enough to be working by the time anxiety-provoking preparations begin. A recommended regimen is as follows: Between 30 and 60 minutes before the operation, staff sedates the client with diazepam 10 mg given orally with a sip of water. If the client weighs less than 35 kg (75 lb.), the dose is reduced to 5 mg. Premedication with a non-steroidal anti-inflammatory drug (NSAID) (for example, ibuprofen 800 mg) may also be used to reduce uterine cramping. Atropine is administered before anesthesia to prevent bradycardia and lessen the possibility of vasovagal syncope and cardiac arrest. If additional sedatives or narcotic analgesics are utilized, the minimum dose should be given intravenously by slow injection immediately before the procedure. The client should be on the operating table when IV medications are given and monitored closely.

**INfiltration of Local Anesthesia**

The goal is to achieve an anesthetic block that includes all layers of tissue from skin to peritoneum. The anesthetic will spread both above and below the line of infiltration in the subcutaneous space. It may be necessary to augment the anesthesia as the fascial and peritoneal layers are exposed. In addition, lidocaine may be dripped on each tube for additional anesthesia before performing occlusion. The total dose of lidocaine 1% without epinephrine should not exceed 5 mg/kg [20 ml for 40-kg (88 lb.) body weight]. If the lidocaine is supplied in 2% strength (10 ml for 40 kg body weight), it can be diluted with normal saline or sterile water for injection. The 1% strength results in better volume for more effective infiltration. (Some doctors prefer to dilute even further, to 40 ml of 0.5% strength.)

**Protocol for Local Infiltration**

The "diamond-shaped" and "fan-shaped" anesthesia blocks are two alternative techniques.

In the diamond-shaped technique, the needle enters the skin in the midline of the incision site, and is inserted in both lateral directions along the incision line. Through the same puncture site, the needle is inserted at a 45-degree angle to the fascia in four directions, thus creating the diamond shape. A 90-degree infiltration of the peritoneum completes the procedure. The fascia and peritoneum are infiltrated with 2-3 ml lidocaine in each direction. Make sure aspiration is carried out each step prior to infiltration.
Field block using the diamond-shaped technique

(a) Entry of the needle at the incision site

(b) Skin infiltration

(c) Infiltration of the different layers
In the fan-shaped technique, the needle is inserted at one end of the skin incision site and along the incision line. Through the same puncture site, the needle is inserted at a 45-degree angle to the fascia. The needle is then withdrawn to the subcutaneous tissue and inserted at 90 degrees, and straight down going through the rectus sheath and muscle into the peritoneum, thus creating the fan shape. In each step, the local anesthetic is infiltrated along the needle track as the needle is withdrawn slowly. Six to eight ml lidocaine is injected into the fascia and 2-3 ml into the peritoneal layer. Aspiration is done after every injection and prior to infiltration.

**Field block using the fan-shape technique**

**(a) Skin infiltration**

![Image of skin infiltration](Image)

**(b) Infiltration of the different layers**

![Diagram of infiltration](Image)

To spread the anesthetic into the tissues, the doctor gently massages the skin.

A 2–3-minute waiting period enables the anesthetic to take effect. The anesthesia is tested. If the client can feel a needle prick, the doctor waits an additional 2–3 minutes and tests again. The lidocaine that is remaining in the syringe (about 5 ml) is reserved for supplemental use on the fascia, peritoneum, and tubes, as needed.
MONITORING VITAL SIGNS

Client vital sign monitoring must be thoroughly ingrained in staff members’ minds as part of the routine practice of minilaparotomy. All staff members should receive training in the method and frequency of monitoring the client. Local anesthetic and analgesic agents and sedatives may cause respiratory depression, cardiovascular depression, hypersensitivity reactions, and central nervous system toxicity. Knowledge of the etiology and symptomatology of these reactions enables intervention that may prevent severe complications.

Staff must recognize normal and abnormal reactions to drugs used during the procedure. Changes in the client’s condition must be noted. Monitoring and recording blood pressure, pulse, and respiration rate are part of the staff’s responsibilities. Vital signs are checked before, during, and after the operation until the client is fully recovered. The frequency of monitoring should follow these guidelines:

**Preoperative:** Blood pressure, pulse, and respiration should be monitored and recorded before and after the preoperative dose of sedative is given. This provides the baseline data for the client.

**Intraoperative:** A staff member of the team should monitor and record blood pressure, pulse, and respiration at least three times during surgery. To assess the status of analgesia, the staff member should converse with the client continually.

**Postoperative:** Blood pressure, pulse, and respiration must be monitored and recorded at least every 15 minutes until stable (i.e., vital signs have returned to preoperative levels). Under no circumstances should the client be left alone.

PHARMACOLOGY OF DRUGS RELEVANT TO LOCAL ANESTHESIA

**Lidocaine Hydrochloride (Xylocaine, lignocaine)**

*Action:* Local anesthetics act by preventing generation and transmission of impulses along nerve fibers and at nerve endings. Although toxicity occasionally occurs as a result of overdose with local anesthetics, allergic reactions to the amide-linkage drugs, such as lidocaine and bupivacaine, are exceedingly rare. In fact, it is questionable whether true anaphylaxis to lidocaine given *without* epinephrine has ever been shown.

*Dosage:* The usual dose for minilaparotomy under local anesthesia is 20 ml of 1% lidocaine. The maximum safe dose of 1% lidocaine without epinephrine is 5 mg/kg body weight. For a woman weighing 40 kg (88 lb.), this is equivalent to 200 mg, or 20 ml, of 1% lidocaine (or 10 ml of 2% lidocaine).

*Regimen:* Through a single incision site, the doctor locally infiltrates 1% lidocaine without epinephrine, about 15 ml, into the skin, fascia, and peritoneum. After waiting 2–3 minutes for the local field block to take effect, the doctor may begin surgery. The remaining 5 ml of the lidocaine is used to augment the anesthesia block as needed.

One may elect to use 0.5% lidocaine and inject a greater volume. However, 2% solutions should routinely be diluted with normal saline to make a 1% strength, because the more concentrated 2% solution (with a maximum dose of 5 mg/kg) will not allow enough volume to provide adequate infiltration of all tissue layers, and if accidentally injected into the blood stream may be cardiotoxic.

*Warnings:* Adverse effects may occur as a result of the addition of a vasoconstrictor (epinephrine).

Adverse effects of lidocaine on the central nervous system and cardiovascular system are seen after accidental intravenous injection. The client usually first complains of numbness of the tongue and
mouth, lightheadedness, tinnitus, visual disturbances, and slurring of speech. She may lose consciousness and have convulsions. If the injection is stopped, the drug passes rapidly, and the convulsions will stop within 2 minutes. Coma can occur if the intravenous dose is very high (2% injected rapidly).

The doctor must pull back the plunger of the syringe when injecting each tissue layer to ensure that the solution is not being injected into a vessel; all injections are to be given slowly.

**Meperidine Hydrochloride (Pethidine, Demerol)**

**Action:** Meperidine is a narcotic analgesic similar to morphine, used for preoperative medication as an adjunct to local anesthesia and for the relief of pain that might result from the procedure.

**Dosage:** The usual initial adult dose for analgesia as a preoperative medication for ML/LA is 50 mg, given intravenously. If the client is experiencing pain during the procedure, staff may administer an additional dose, up to 25 mg. The initial dose of 50 mg should be reduced by one-half (down to 25 mg) for clients weighing less than 35 kg (75 lb.).

**Regimen:** Before surgery, with the client on the operating table, staff gives half of the drug intravenously over a period of 30 seconds, and note any negative effects. If client has none, staff gives the remaining dose over another period of 30 seconds. If the client becomes excessively drowsy after the first half of the dose, the second half is not injected.

**Warnings:** Respiratory depression, hypotension, and profound sedation or coma may result when meperidine is combined with a sedative, such as diazepam or midazolam. Only persons specifically trained in the use of intravenous medications, in monitoring anesthesia, and in the management of the respiratory depression that may result should administer intravenous meperidine. Rapid intravenous injection of meperidine increases the incidence of adverse reactions.

Like other narcotics, meperidine may produce orthostatic hypotension in ambulatory patients. Clients may experience side effects when starting to ambulate. The most frequently observed adverse reactions include lightheadedness, dizziness, sedation, nausea, vomiting, and sweating. These reactions may be alleviated if the client lies down.

When meperidine is used intravenously, naloxone, oxygen, and resuscitative equipment must be readily available for reversal of respiratory depression.

**Note:** Staff must instruct clients receiving meperidine not to drive a vehicle or operate machinery for 24 hours.

**Treatment of overdose:** One should administer oxygen, intravenous fluids, vasopressors, and other supportive measures as indicated. As a specific antidote, an immediate intravenous dose of naloxone is given (see page 62).

**Nalbuphine Hydrochloride (Nubain)**

**Action:** Nalbuphine is a potent analgesic, essentially equivalent to morphine. Its onset of action is within 2–3 minutes after intravenous administration. The effects of the drug last for 3–6 hours.

**Dosage:** The usual adult dose is 10 mg/70 kg (150 lb.). Nalbuphine is supplied in two formulations, either 10 mg/ml or 20 mg/ml, so the volume in milliliters administered must be based on the strength of the formulation.

**Regimen:** To provide analgesia to accompany the use of local anesthesia for outpatient procedures, staff give nalbuphine intravenously on the operating room table, just prior to the surgery.
**Warnings**: Only persons specifically trained in the use of intravenous medications, in monitoring anesthesia, and in the management of the respiratory depression that may result should administer nalbuphine. Nalbuphine may cause significant respiratory depression.

Naloxone, oxygen, and resuscitative equipment should be readily available.

The most frequent adverse reaction is sedation. Other reactions are sweaty or clammy skin, nausea or vomiting, dizziness or vertigo, dry mouth, and headache.

**Note**: Staff must instruct clients receiving nalbuphine not to drive a vehicle or operate machinery for 24 hours.

**Treatment of overdose**: Staff administers oxygen, intravenous fluids, vasopressors, and other supportive measures as indicated. As a specific antidote, an immediate intravenous dose of naloxone is given (see below).

**Naloxone Hydrochloride (Narcan)**

**Action**: Naloxone is indicated for the reversal of respiratory depression caused by narcotics, including meperidine (pethidine, Demerol), nalbuphine (Nubain), butorphanol (Stadol), fentanyl (Sublimaze), and pentazocine (Talwin). Naloxone has no toxicity.

**Dosage**: The initial dose is 0.4 mg given intravenously. Staff gives repeat doses intravenously at intervals of 2–3 minutes until the desired degree of reversal (adequate ventilation and alertness) is achieved. Several doses of naloxone, up to 2 mg, even over a short period, may be given without untoward effects.

**Regimen**: Naloxone is administered intravenously for a rapid onset of action apparent within 2 minutes. The requirement for repeat doses of naloxone will depend on the amount, type, and route of administration of the narcotic being antagonized.

**Warnings**: If staff observes no response after a total dose of 2 mg, they should consider other causes of respiratory depression, such as overdose of diazepam or hypoxia due to internal hemorrhage.

Staff must monitor the client closely because the effect of the narcotic causing the depression may outlast the effect of naloxone.

Naloxone is not effective against respiratory depression due to non-narcotic drugs, such as diazepam and midazolam.

In addition to naloxone, resuscitative measures such as maintenance of a free airway, artificial ventilation, cardiac massage, and vasopressor agents must be available and employed when necessary to counteract acute narcotic oversedation.

Naloxone ampules and vials show an expiration date. Because this drug is not used frequently, the supply may not be fresh. Injections repeated at shorter intervals, or increased doses, may be needed for effectiveness if the expiration date has passed. Efforts should be made to insure unexpired medication.

**Promethazine Hydrochloride (Phenergan)**

**Action**: Promethazine is a phenothiazine tranquilizer. It has antihistaminic, sedative, antiemetic, and anticholinergic effects. Promethazine can be used in ML/LA for preoperative sedation, for prevention and control of nausea and vomiting, and as an adjunct to analgesics for control of intraoperative and postoperative pain.
**Dosage:** For preoperative and postoperative medication, the usual adult dose is 25 mg or 50 mg.

**Regimen:** For anesthesia premedication, promethazine is administered intramuscularly.

**Warnings:** Promethazine adds to the sedative effect of narcotics. If it is given with meperidine before a minilaparotomy, the dose of meperidine should be reduced by \( \frac{1}{4} \) to \( \frac{1}{2} \).

Administration of promethazine should not be intravenous or subcutaneous, because this may result in tissue necrosis.

**Diazepam (Valium, Anxionil)**

**Action:** Diazepam is a benzodiazepine with anticonvulsant, anxiolytic, sedative, muscle-relaxant, and amnesic properties. Diazepam is a useful premedication for clients who will undergo ML/LA, to induce a calming effect.

**Dosage:** For clients over 35 kg (75 lb.), the dose is 10 mg given orally. If a client weighs less than 35 kg, the dose should be reduced to 5 mg given orally. One should use a lower dose (usually 2–5 mg) for debilitated clients.

**Regimen:** Diazepam can be given by mouth, at least 30 minutes before the procedure, with a sip of water.

Diazepam may be given intravenously at the start of the procedure only when the solution is injected slowly—at least 1 minute for each 5 mg (1 ml) given. It must not be injected into small veins, such as those on the back of the hand or the inside of the wrist. Extreme care must also be taken to avoid intra-arterial administration or extravasation. When administered intravenously, diazepam must not be diluted or mixed with other solutions or drugs in the syringe. If diazepam cannot be administered directly intravenously, it may be injected slowly through the infusion tubing as close as possible to the needle insertion site. Intramuscular administration for premedication usage is to be avoided, since the duration of maximum effect is not predictable.

When diazepam is used with a narcotic analgesic, such as meperidine, as the preoperative medication for ML/LA, staff should reduce the narcotic dosage by at least one-third and administer it in small increments. In some cases, the use of a narcotic may not be necessary.

**Warnings:** When diazepam is combined with the use of a narcotic (such as meperidine) or other sedative, respiratory depression is increased. Therefore, oxygen and resuscitative equipment must be readily available. Side effects most commonly reported are drowsiness, fatigue, and ataxia. Other side effects are bradycardia, cardiovascular collapse, and hypotension.

Manifestations of diazepam overdose include somnolence and confusion.

Diazepam and ketamine, being chemically incompatible because of precipitate formation, should not be injected in the same syringe.

**Treatment of overdose:** Staff administer an antidote, such as physostigmine 0.5–1.0 mg intravenously, or flumazenil 0.2 mg intravenously, given over 30 seconds, with subsequent doses of 0.3 mg and then 0.5 mg given at 1-minute intervals up to a total dose of 3 mg.

**Note:** Naloxone used to reverse narcotic sedation will not reduce the sedation caused by diazepam.

**Midazolam Hydrochloride (Versed, Dormicum)**

**Note:** Midazolam should only be used with continuous oxygen saturation monitoring.
**Action:** Midazolam is a short-acting benzodiazepine that depresses the central nervous system; it is 3 1/4 times as potent as diazepam. It can be used as a preoperative sedative to induce a calming effect and to diminish the client's recall of a ML/LLA. It can be used either alone or with a narcotic.

**Dosage:** For intramuscular preoperative sedation, the client may be given 5 mg (0.07–0.08 mg/kg body weight) about 1 hour before surgery. (This dose may be too high for many clients). A maximum dose of 3 mg is preferred. At a formulation of 1 mg/ml, the maximum dose would be 3 ml. For intravenous preoperative sedation, the initial dose is 0.5–1.0 mg. To achieve optimal sedation an additional 1.0 – 1.5 mg IV is given, however staff should carefully assess effects of Midazolam first. For debilitated clients, lower doses may be sufficient.

**Regimen:** Midazolam is administered intramuscularly or by slow intravenous route for preoperative sedation. Staff should not administer midazolam rapidly or as a single bolus intravenously. The 1-mg/ml formulation is recommended to facilitate slower injection. It may be diluted with 0.9% sodium chloride or 5% dextrose in water.

If narcotic premedication or other central nervous system depressants are used, patients will require 30% less midazolam.

**Warnings:** Intravenous midazolam has been associated with respiratory depression and respiratory arrest, especially when used for conscious sedation. In some cases, where staff have not recognized this promptly and treated it effectively, death or hypoxic encephalopathy has resulted.

Only hospitals or ambulatory care settings that provide for continuous monitoring of respiratory and cardiac function should use intravenous midazolam.

Resuscitative drugs and equipment and staff trained in their use must be immediately available.

It is unclear whether midazolam is excreted in human milk, so caution is necessary when the client is a nursing mother.

**Treatment of overdose:** Treatment is the same as that for diazepam. Staff administer an antidote intravenously, such as phystostigmine, 0.5–1.0 mg intravenously, or flumazenil, 0.2 mg given intravenously over 30 seconds, with subsequent doses of 0.3 mg and then 0.5 mg given at 1-minute intervals up to a total dose of 3 mg.

**Note:** Naloxone will not reduce the sedation caused by midazolam

Below are recommendations for moderate analgesia and sedation for BTL/MLLA.

Session 8

EMERGENCY PREPAREDNESS

OVERVIEW

For any surgical procedure using anesthetic regimen, careful and frequent monitoring of the client includes assessment of vital signs, level of consciousness, comfort, and sense of well-being. Monitoring before, during and after the procedure makes the surgical staff to detect possible complications requiring immediate emergency measure related to anesthesia or to the surgery.

This session provides service providers with the knowledge and skills in being prepared for emergency cases.

LEARNING OBJECTIVES

At the end of the session, the participants will be able to:

1. Discuss what staff must know and be able to do for emergency preparedness.
2. Enumerate equipment and drugs necessary for emergencies.
3. Explain what to do if the facility providing services have limited capabilities for handling emergencies.

PREPARATION

- PowerPoint slides on “Emergency Preparedness”
- Computer and LCD
- Whiteboard and appropriate marker

TIME ALLOTMENT

30 minutes
<table>

</thead>
<tbody>
<tr>
<td><strong>Emergency Preparedness</strong></td>
<td>Introduce the session by providing an “Overview” of the session.</td>
</tr>
</tbody>
</table>

**Learning Objectives**
- Discuss what staff must know and be able to do for emergency preparedness.
- Enumerate equipment and drugs necessary for emergencies.
- Explain what to do if the facility providing services have limited capabilities for handling emergencies.

**Components**
- Ability to recognize and manage early warning signs and complications
- Client monitoring for early recognition of complications
- Availability of functional equipment and adequate supplies, and appropriate drugs
- Hospital back-up

**Emergency Drugs**
- Epinephrine
- Atropine
- Naloxone
- Corticosteroid
- Dopamine
- Sodium Bicarbonate
- Furosemide
- Physostigmine
- Aminophylline
- Antihistamine
- Diazepam

State the “Learning Objectives” of the session as presented on the slide.

Explain the components of “Emergency Preparedness” using the slide.

Enumerate “Emergency Drugs” as presented on the slide.
### The Emergency Trolley

Ask participants to name the contents, as pointed, of an emergency trolley.

These are:
- IV fluid
- Cotton balls
- Ambu bag
- Emergency drugs
- Tourniquet
- Syringe and needle
- Venoset
- Plaster

### Equipment for ML-LA Services

Enumerate the emergency equipment.

### Hospital Back-Up

Tell participants that:
- If minilaparotomy is provided in a clinic with limited capability for handling emergencies (such as a mobile service facility) special planning is necessary.
- There should be formal relationships with established backup medical facilities in the area so that clients who need continued medical treatment during and after emergencies can receive reliable care.
- The local backup facilities must have the supplies, equipment, and trained staff required to handle complications following minilaparotomy.

### Conclusion

Review the “Learning Objectives” of the session and ask participants if such were achieved.
NARRATIVE

STAFF PREPARATION FOR EMERGENCIES

Staff must take certain precautions and make preparations prior to minilaparotomy procedures to effectively manage emergencies. Staff must be skilled in administration of intravenous fluids and drugs. They must understand which drugs may be used, how to administer them, and their expected actions. They must be familiar with the use of all emergency equipment and must check all such equipment before each operating session. Members of the staff must be trained to handle specific complications. The staff monitoring the client in the operating and the recovery must be aware of early signs of complications and be able to take initial emergency action. At least one member of the surgical team must know how to administer cardiopulmonary resuscitation.

EMERGENCY EQUIPMENT

The equipment below must be available for emergency use in the operating room and recovery area. All emergency equipment must be immediately available, prepared for use, and in good functioning condition. A laryngoscope and endotracheal tubes are appropriate only when trained and experienced personnel are available to use them. A battery-operated light source should be available for backup or focused illumination of the operative site.

- Stethoscope/sphygmomanometer
- Nasopharyngeal/Oropharyngeal airways
- Oxygen tank with pressure-reducing valve, flow meter, rubber tubing and face mask
- Suction apparatus manual with tubing and two straps
- Manual resuscitator with face mask
- Ambu bag
- Intravenous fluids and sterile infusion sets with large calibre needles
- Emergency drugs
- Full set of sterilized laparotomy instruments
- Emesis basin, mouth wipes, flashlights
- Syringes and needles
- Gauze pads and adhesive tapes

EMERGENCY DRUGS

The drugs listed in Table 8.2 must be readily available in the operating room and recovery area. Staff need to be well informed about the drugs; their use, dose, strength, and route of administration; signs of toxicity; and treatment of overdose.

</tr>
<tr>
<td>Furosemide 10mg/amp. In 2ml amp</td>
<td>Used as diuretic in cases in cardio-pulmonary edema/congestion in emergency situation.</td>
<td>Initial dose of 40 mg by slow IV. High doses of 80mg by continuous infusion; can be increased by 20 mg increment every 1-2 hrs until response</td>
<td>Should monitor fluid input and output and serum potassium</td>
<td>This is a well-tolerated drug with very rare occurrence of allergic reaction</td>
</tr>
<tr>
<td>Aminophylline</td>
<td>Bronchospasm with pulmonary edema during emergency situation</td>
<td>Loading dose 5-6 mg/kg in 50-100 ml diluent over 30 min.</td>
<td>Monitor cardiac/pulse rate, blood pressure</td>
<td>Bronchodilator with mild diuretic property and positive chronotropic and inotropic effect.</td>
</tr>
<tr>
<td>Sodium bicarbonate</td>
<td>Metabolic acidosis due to low oxygen saturation during shock or cardiac arrest.</td>
<td>Slow IV of 1 mEq/kg repeated 0.5 mEq/kg every 10 min.</td>
<td>Should have frequent laboratory monitoring of blood oxygen saturation</td>
<td>Works by mixing with lactic acid that forms during shock or cardiac arrest.</td>
</tr>
</tbody>
</table>

Promethazine is also used as an adjunct to prevent nausea from pre-surgical medications.
HOSPITAL BACKUP

If minilaparotomy is provided in a clinic with limited capability for handling emergencies (such as a mobile service facility) special planning is necessary. Mobile service teams must have all the supplies and equipment needed to handle the immediate surgical emergency. In addition, they should have formal relationships with established backup medical facilities in the area so that clients who need continued medical treatment during and after emergencies can receive reliable care. The local backup facilities must have the supplies, equipment, and trained staff required to handle complications following minilaparotomy.
THE SURGICAL PROCEDURE

OVERVIEW

Programs must ensure the safety of women undergoing MLLA. Surgeons must be trained and skilled in the techniques they are using, in the use of appropriate and safe anesthesia, in the proper use of a uterine elevator, in emergency abdominal surgery, and in other procedures for managing emergencies. The staff ensures safety by maintaining strict infection prevention practices.

This session provides the necessary information and skills, through practice with a Zoe pelvic model, on the steps of performing BTL by minilap.

LEARNING OBJECTIVES

At the end of the session, the participants will be able to:

1. Describe the two approaches to BTL by minilap.
2. Discuss the steps of the suprapubic approach to BTL by minilap.
3. Demonstrate the steps of minilap by the suprapubic approach, using a pelvic (Zoe) model.
4. Discuss the steps of the subumbilical approach to BTL by minilap.
5. Demonstrate the steps of minilap by the subumbilical approach, using a pelvic (Zoe) model.

PREPARATION

- PowerPoint slides on “The Surgical Procedure”
- Computer and LCD
- Whiteboard and appropriate marker
- Zoe pelvic model
- Instruments for minilap: 1 set of Apelo retractors, uterine elevator, Graves vaginal speculum, 2 straight Kelly forceps, 2 curved Kelly forceps
- Copies of “Performance Checklist On Minilaparotomy Under Local Anesthesia”

TIME ALLOTMENT

3 hours and 45 minutes
REFERENCES

## The Surgical Procedure

### Learning Objectives

1. Describe the 2 approaches to BTL by minilap.
2. Discuss the steps of the suprapubic approach to BTL by minilap.
3. Demonstrate the steps of minilap by the suprapubic approach, using a pelvic (Zoe) model.
4. Discuss the steps of the subumbilical approach to BTL by minilap.
5. Demonstrate the steps of minilap by the subumbilical approach, using a pelvic (Zoe) model.

### Approaches to Minilap

<table>
<thead>
<tr>
<th>Suprapubic Minilaparotomy</th>
<th>Subumbilical Minilaparotomy</th>
</tr>
</thead>
</table>

- Suprapubic Minilaparotomy
- Subumbilical Minilaparotomy
Tell participants that:

- The suprapubic approach is appropriate for clients at any time in their menstrual cycle for as long as it is reasonably sure that she is not pregnant.
- This procedure is also appropriate for most post-abortion clients and for clients who are 42 or more days postpartum (i.e., once the uterus is fully involuted).

Enumerate the steps of the suprapubic approach to minilap.

Discuss the steps using the slides.

### Steps

1. Evaluate the client
2. Prepare the client before entering the operating room
3. Prepare instruments
4. Position the client appropriately
5. Insert the uterine elevator
6. Prepare the abdominal area
7. Select the incision site
8. Infiltrate local anesthesia
9. Enter the abdomen
10. Access and deliver the tubes
11. Occlude the tubes
12. Close the abdomen
13. Perform after care

### 1. Evaluating the Client

- Review the client’s medical history and physical examination results from the medical record
- Verify the client’s informed decision and consent
- Check client’s vital signs
- Confirm by history and by reexamination the absence of pregnancy, infection, or any other conditions that could require delaying the procedure

### 2. Client Preparation

- Verify that the client understands the most important steps of the procedure
  - What local anesthesia means
  - What she might feel at various times
  - That her cooperation will be needed at various parts of the surgery
- Ask client to empty her bladder
- Provide surgical gown to the client and a private place to change
3. Prepare Instruments

Instruments used for inserting the uterine elevator

Ask participants to name the instruments. Supplement as needed.

3. Prepare Instruments

Instruments used for performing minilaparotomy

4. Positioning the Client

- Escort the client to the operating room and onto the operating table
- Variations in client positioning for uterine elevator insertion

The dorsal lithotomy position

The dorsal supine position

5. Inserting the Uterine Elevator

- The uterine elevator brings the uterine cornual portion of the tubes close to the incision
- The surgeon inserts the uterine elevator
- A pelvic examination is performed before insertion
5. Inserting the Uterine Elevator

**Steps**

1. Position the client comfortably on the surgical table in the dorsal supine position
2. Insert the vaginal speculum into the vagina to expose the cervix
3. Use both screws to open the 2 blades of the speculum
4. Swab the cervix and the vaginal walls with antiseptic
5. Pass the uterine elevator through the vagina and into the cervix, up to the cervical guard

6. Preparing the Abdominal Area

**Steps**

1. Insert IVF and administer sedative and analgesic
2. Using a swab soaked with antiseptic, wipe the skin starting from the intended incision site line and going outwards in a circular fashion
3. Extend swabbing to the upper part of the pubis and thighs. Repeat twice, discarding the swab after each time
4. Allow antiseptic to dry.
5. Create a sterile field by placing sterile drapes around the immediate operative site.
7. Selecting the Incision Site

**Steps**

1. Surgeon selects an incision site that is anatomically appropriate to facilitate access to the tubes
   - Suprapubic incision 2 to 3 cm above the border of the pubis

8. Local Anesthesia Infiltration

**Steps**

1. Warn the client that her skin will now be anesthesized to reduce pain. Tell her that she may feel the initial sharp pain “prick” followed by a burning sensation
2. Introduce the needle at one end of the planned incision site, inserting the entire needle into the intradermal tissue and horizontally beneath the skin along the length of the incision site.
3. Once the needle is completely inserted, aspirate to ensure that the needle has not hit a blood vessel.
4. Inject lidocaine along the planned incision line while slowly withdrawing the needle up to the site of entry.
5. Repeat infiltration at 45 and 90 degrees angle relative to the skin.
6. Gently massage the area to evenly distribute the anesthetic.
7. Wait 2-3 minutes.

9. Entering the Abdomen

- Surgeon and assistant work together with specific tasks:
  - Surgeon:
    - Incises and dissects the abdominal wall layers
    - Accesses and identifies the tubes
    - Provides direction to the assistant on how to help
  - Surgical assistant
    - Exposes the abdominal layers
    - Holds the retractors, as needed, to maintain the incision opening
    - Actively follows the surgery and assists in accordance with the surgeon’s instructions
9. Entering the Abdomen

Steps
1. Check for effective anesthesia by pinching the anesthesized skin with toothed forceps.
2. Make a 3 cm (maximum of 5 cm.) long incision in the midline. Do not include the subcutaneous tissue.

Steps
3. Bluntly dissect the subcutaneous fat up to the fascia using Kelly forceps or the blade of the retractors.
4. Incise the fascia using a scalpel at the center of the incision. Grasp the fascia on both sides with Allis or Kelly forceps.

Steps
5. Bluntly dissect the underlying muscle from the fascia.
6. Extend the fascial opening vertically on both sides so that it is larger than the length of the skin incision to expose the underlying muscle.

Steps
7. Bluntly separate the rectus muscles vertically at the linea alba.
9. Entering the Abdomen

Steps
8. After the rectus muscles are separated, have the surgical assistant reposition the retractors further into the incision to expose the preperitoneal fat.

9. Entering the Abdomen

Steps
9. Operating table is placed in the Trendelenburgh position, as needed.
10. Bluntly dissect the preperitoneal fat, as needed, to expose the peritoneum.
11. Grasp the thinned out peritoneum at two points with hemostats.
12. Check for translucency using the edge of the blade holder.
13. Make a small opening in the peritoneum. Place retractors into the peritoneal opening.

10. Accessing and Delivering the Tubes

Steps
1. Elevate the uterus by depressing the uterine elevator with one hand.
2. Clear the uterus of omentum and bowels which may be covering it.
3. While directly viewing the uterine fundus and keeping the uterine elevator depressed, gently rotate the handle in the opposite direction of the tube being accessed.
10. Accessing and Delivering the Tubes

**Steps**

4. When tube is visualized, grasp it with baby Babcock or Kelly forceps with the free hand. Keep the uterine elevator in place (depressed and rotated).

5. Release the uterine elevator while holding the tube with forceps.

6. Confirm identity of the tube by "walking through" the tube until the fimbriated end is visualized.

11. Occluding the Fallopian Tubes

**Steps**

1. Place the forceps at the midsection of the tube (about 2-3 cm from the cornual portion of the tube).

2. Hold the loop of tube vertically.

3. Tie the loop of tube (approx. 2 cm) with a rapidly absorbable suture (chromic 2-0).

4. Cut off 1 cm of the loop of fallopian tube above the knot using Metzenbaum scissors leaving at least 0.5 cm. tubal stump above the knot. Check for bleeding.
12. Closing the Abdomen

**Steps**

1. Close the fascia using continuous interlock sutures.
2. Close the skin with interrupted or continuous cuticular stitches using absorbable sutures.
3. Dress the closed incision.

13. After Care

**Steps**

- Remove the uterine elevator.
- Place all used instruments in decontaminating solution
- Immerse gloved hands in decontaminating solution.
- Remove gloves appropriately.

Encourage participants to ask questions, and comment on the procedure (which steps they think may be difficult to perform).

Respond to participants’ concern and issues.

Ask a co-facilitator or one of the participants to act as a “client” for BTL/MLLA.

Review the checklist for the steps of suprapubic minilaparotomy with the participants.

Tell participants that they will refer to the checklist in providing feedback to the demonstration.

Demonstrate the steps of performing BTL/MLLA using the Zoe pelvic model. The demonstration includes a role play of communicating to the
client.

After the demonstration, ask participants for feedback.

Participants will work in pairs in practicing the steps of performing BTL/MLLA. Each of the pairs alternate playing the role of service provider/surgeon and client. Facilitators observe and provide feedback on the performance of the surgeon using the checklist.

Participants practice the steps and facilitators coach them until competency is reached.

Introduce the second approach to BTL by minilap by telling participants that:

- Subumbilical minilaparotomy is used for postpartum clients when the uterus is enlarged and easily accessible through a subumbilical approach.

Enumerate the steps of subumbilical minilaparotomy as presented on the slide.

Explain each of the steps using the slides.

1. Evaluating the Client

- Review the client's medical record for the medical history and physical examination results
- Verify the client's informed decision and consent
- Check client's vital signs
- Determine condition of the baby.
2. Client Preparation

- Verify that the client understands the most important steps of the procedure
  - What local anesthesia means
  - What she might feel at various times
  - That her cooperation will be needed at various parts of the surgery
- Ask client to empty her bladder
- Provide surgical gown to the client and a private place to change

3. Positioning the Client

- Escort the client to the operating room and onto the operating table
- Position client in the dorsal supine position
- Assess height of the uterine postpartum fundus

4. Preparing the instruments

Instruments used for performing minilaparotomy

5. Preparing the Abdominal Area

Steps
1. Insert IVF and administer sedative and analgesic
2. Using a swab soaked with antiseptic, wipe the skin starting from the intended incision site line and going outwards in a circular fashion
5. Preparing the Abdominal Area

Steps
3. Allow antiseptic to dry.
4. Create a sterile field by placing sterile drapes around the immediate operative site.
5. Administer additional medications, as needed.

6. Selecting the Incision Site

Steps
1. Surgeon selects an incision site that is anatomically appropriate to facilitate access to the tubes

7. Local Anesthesia Infiltration

Steps
1. Warns the client that her skin will now be anesthesized to reduce pain. Tell her that she may feel the initial sharp pain “prick” followed by a burning sensation
2. Introduce the needle at one end of the planned incision site, inserting the entire needle into the intradermal tissue and horizontally beneath the skin along the length of the incision site.
3. Once the needle is completely inserted, aspirate to ensure that the needle has not hit a blood vessel.
4. Inject lidocaine along the planned incision line while slowly withdrawing the needle up to the site of entry.
5. Repeat infiltration ensuring that the layers (thinned out in this area) are infiltrated.
6. Gently massage the area to evenly distribute the anesthetic.
7. Wait 2-3 minutes.
8. Entering the Abdomen

- Surgeon and assistant work together with specific tasks:
  - Surgeon:
    - Incises and dissects the abdominal wall layers
    - Accesses and identifies the tubes
    - Provides direction to the assistant on how to help
  - Surgical assistant
    - Exposes the abdominal layers
    - Holds the retractors, as needed, to maintain the incision opening
    - Actively follows the surgery and helps, as needed

Steps

1. Check for effective anesthesia by pinching the anesthesized skin with toothed forceps.
2. Make a 3 cm (maximum of 5 cm.) long incision in the midline. Do not include the subcutaneous tissue.
3. Bluntly dissect the subcutaneous fat up to the fascia using a Kelly forceps or the blade of the retractors.
4. Incise the fascia using a scalpel at the center of the incision. Grasp the fascia on both sides with Allis or Kelly forceps.
5. Separate the fascia from the underlying peritoneum. Extend the fascial opening on both sides so that it is slightly larger than the length of the skin incision.
6. Operating table is placed in the Trendelenburgh position, as needed.
7. Grasp the thinned out peritoneum at two points with hemostats.
8. Entering the Abdomen

Steps
8. Check for translucency using the edge of the blade holder.
9. Make a small opening in the peritoneum.
10. Place retractors into the peritoneal opening to expose the uterus. Clear the uterus of omentum and bowels which may be covering it.

9. Accessing and Delivering the Tubes

Steps
1. Using manual, external pressure on the abdomen, gently push the uterus toward the opposite side of the tube being accessed while the surgical assistant moves the retractors to bring the incision to the cornual area.
2. Once the tube has been visualized, grasp it with forceps.
3. Gently pull out the tube until the fimbria is visualized.
4. Confirm identity of the tube by “walking through” the tube until the fimbriated end is visualized.
10. Occluding the Fallopian Tubes

Steps
1. Place the forceps at the midsection of the tube (about 2-3 cm from the cornual portion of the tube).
2. Hold the loop of tube vertically.
3. Tie the loop of tube (approx. 2 cm) with a rapidly absorbable suture (chromic 2-0).
4. Cut off 1 cm of the loop of fallopian tube above the knot using Metzenbaum scissors leaving at least 0.5 cm tubal stump above the knot. Check for bleeding.

11. Closing the Abdomen

Steps
1. Close the fascia using continuous interlock sutures.
2. Close the skin with interrupted or cuticular stitches using absorbable sutures.
3. Dress the closed incision.

Remind participants that:
- The tubes may be edematous during the immediate postpartum period.
- As such, the surgeon must ensure that a segment of the tubes are excised.

Encourage participants to ask questions, and comment on the procedure (which steps they think may be difficult to perform).

Respond to participants’ concern and issues.
Ask a co-facilitator or one of the participants to act as a “client” for BTL/MLLA.

Review the checklist on the steps for subumbilical minilaparotomy with the participants.

Tell participants that they will refer to the checklist in providing feedback to the demonstration.

Demonstrate the steps of performing BTL/MLLA using the Zoe pelvic model. The demonstration includes a role play of communicating to the client.

After the demonstration, ask participants for feedback.

Participants will work in pairs in practicing the steps of performing BTL/MLLA. Each of the pairs alternate playing the role of service provider/surgeon and client. Facilitators observe and provide feedback on the performance of the surgeon using the checklist.

Participants practice the steps and facilitators coach them until competency is reached.

**Conclusion**

Ask participants at random to enumerate the steps of “suprapubic minilaparotomy” and “subumbilical minilaparotomy”.

Discuss with participants the schedule of clinical practicum in their sites.
Programs must ensure the safety of women undergoing ML/LA. Surgeons must be trained and skilled in the techniques they are using, in the use of appropriate and safe anesthesia, in the proper use of a uterine elevator, in emergency abdominal surgery, and in other procedures for managing emergencies. The staff ensures safety by maintaining strict infection prevention practices. She also carefully screens and selects clients, and addresses any conditions that may increase the risks associated with the procedure. During counseling, staff presents minilaparotomy as a permanent method of contraception. Nevertheless, some clients request reversals after undergoing the procedure, so it is important for doctors to use occlusion techniques that are effective yet minimize damage to tubes.

The facility and its equipment affect the safety of the client. The facility must handle an adequate volume of procedures so that the doctors and other members of the surgical team can maintain their skills. However, program managers should discourage surgical personnel from doing an excessive number of procedures in a single session or operating at an excessive speed, because these practices may lead to an increase in complications and failure rates as a result of operator fatigue. The facility must be equipped with drugs to handle life-threatening situations and other emergencies. All instruments and equipment must be in optimum working condition before the start of the surgical procedure.

SUPRAPUBIC MINILAPAROTOMY

The suprapubic procedure is appropriate for clients at any time in their menstrual cycle. This procedure is also appropriate for most postabortion clients and for clients who are 42 or more days postpartum (i.e., once the uterus is fully involuted).

Evaluation of the Client

Although the pre-operative assessment has already been conducted, be sure to perform the following steps before surgery:

- Review the client’s medical history and physical examination results from the medical record.
- Verify the client’s informed decision and consent by asking if she still wants the procedure and why she wants it.
- Check the client’s vital signs.
- Confirm by history and by reexamination the absence of pregnancy, infection, or any other conditions that could require delaying the procedure.

Client Preparation Before Entering the Operating Room

After the client has been evaluated and the decision has been made to proceed with surgery, prepare the client before she enters the operating room, as follows:

- **Verify that the client understands the most important steps of the procedure** (e.g., what local anesthesia means, what she might feel at various times, and that her cooperation may be needed at various parts of the surgery to make the procedure easier)
- **Ask the client to empty her bladder.** A full bladder increases the risk of injury during abdominal entry. Therefore, immediately before the procedure, the client’s bladder must be emptied by
asking her to urinate immediately before entering the operating room. Routine use of the catheter is discouraged as this increases the risk for infection. Use of the catheter is limited only to instances when the bladder is noted to be distended intraoperatively.

- Provide a surgical gown for the client and usher her to a private place to change.

**Position the Client**

Escort the client into the operating room and help her onto the surgical table. Positioning the client for a suprapubic procedure should involve considerations of both client comfort and ease of access to the fallopian tubes is facilitated through the use of the uterine elevator; the most common position used is the dorsal supine position.

**The dorsal supine position**

- Insert the Graves vaginal speculum into the vagina to expose the cervix.
- Use both screws to open the two blades of the speculum, this ensures optimal visualization of the cervix and helps prevent the vaginal walls from coming into contact with the intrauterine portion of the uterine elevator.
- Using a sterile forceps to hold an antiseptic-soaked cotton ball or gauze sponge, generously swab the cervix and vagina with antiseptic solution.
- Without touching the vaginal walls, pass the uterine elevator through the vagina and into the cervix, up to the cervical guard. Be sure to maintain the sterility of the intrauterine portion of the uterine elevator.

**Inserting the Uterine Elevator**

The uterine elevator helps the surgeon manipulate the uterus and gain easier access to the fallopian tubes by bringing the uterine corneal portion of the tubes to the incision site so that each tube can be directly visualized and grasped. Use of the uterine elevator also permits the incision to be small.

The surgeon inserts the uterine elevator. If a pelvic examination has not been done by the surgeon, this should be done before insertion of the uterine elevator. Knowing the size, shape, and direction of the uterus will help decrease the chances of uterine perforation or of difficulty in manipulating the uterine elevator. The uterine elevator is inserted before cleaning the abdomen.

The most widely used technique for inserting the uterine elevator is as follows:

- Position the client comfortably on the surgical table in the dorsal supine position.
- Insert the Graves vaginal speculum into the vagina to expose the cervix.
- Use both screws to open the two blades of the speculum, this ensures optimal visualization of the cervix and helps prevent the vaginal walls from coming into contact with the intrauterine portion of the uterine elevator.
- Using a sterile forceps to hold an antiseptic-soaked cotton ball or gauze sponge, generously swab the cervix and vagina with antiseptic solution.
- Without touching the vaginal walls, pass the uterine elevator through the vagina and into the cervix, up to the cervical guard. Be sure to maintain the sterility of the intrauterine portion of the uterine elevator.
- Remove the speculum, taking care to keep the uterine elevator in place with one hand so that it does not slip out.
- Place a sterile drape on top of the handle of the uterine elevator so it can be manipulated during abdominal surgery without becoming contaminated.

**Preparing the Abdominal Area**

Use an appropriate antiseptic solution to saturate a sterile swab on a sterile sponge forceps.

Using the soaked swab on a sponge forceps, wipe the skin, first with strokes at the site of the planned incision line and then with circular motions around the incision line, moving progressively out to the periphery. Make progressively larger concentric circles from the planned incision line outward, but do not bring the used swab back over a cleaned area.

Upon reaching the periphery of the prepared skin, discard the swab in a waste receptacle. Swabbing should be repeated at least twice. For suprapubic procedures, skin preparation should include the upper part of the pubis and thighs.
Preparing the client’s abdominal area before a suprapubic minilaparotomy

After allowing the antiseptic to dry, create a sterile field by placing sterile drape sheets around the immediate operative site. If four drapes are used, place the drapes above to the head of the client, below to the legs of the client, and on both sides of the operative area, and secure then in place with towel clips. Once the drapes are in place, when placed at right angles they will form a sterile window.

At this point, the client monitor administers by slow IV the sedative and pain medication (e.g., diazepam and meperidine) according to the regimen selected.

Selecting the Incision Site

Before beginning infiltration, the surgeon must select the appropriate incision site. This will ensure that the abdomen is opened in the most optimal area anatomically, one that will facilitate access to the fallopian tubes.

The best area for a suprapubic incision is 2 to 3 cm. above the border of the pubis. In this area, an anatomical fold at the union of the pubis and the abdominal wall is generally thinner, which facilitates opening of the abdomen.
The suprapubic minilaparotomy incision site

Infiltration of Anesthesia: Fan-Shaped Technique

The nurse monitor cleans the vial top with 60-70% isopropyl alcohol and serves the surgeon or nurse assistant by holding the vial as either one draws up 10 cc. of 2% or 20 cc. of 1% lidocaine without epinephrine. The recommended needle gauge is 21 and the needle length is 1.5 in. so the anesthesia can be administered throughout the length of the incision and deep into the abdominal layers in one attempt.

Tell the client that her skin will now be anesthetized to reduce pain. Tell her that she may feel the initial sharp pain “prick” of the needle and a burning sensation while the anesthesia is injected.

At one end of the planned incision site, introduce the needle through the skin, inserting the entire needle into the intradermal tissue and horizontally beneath the skin along the complete length of the planned incision site.

Field block using fan-shape technique

(a) Skin infiltration
Once the needle is completely introduced, and before the anesthetic is injected, gently aspirate it to ensure that the needle has not entered a blood vessel.

Inject lidocaine along the planned incision line while slowly withdrawing the needle until the tip is at the site of entry.

Repeat the infiltration at 30°, 60°, and 90° angles relative to the skin, thus creating a fan shape. This will ensure that all abdominal wall layers are anesthetized down to the peritoneal layer. The needle should be withdrawn slowly while 2 to 3 cc. lidocaine is injected in each layer. Use no more than 20 cc. of 1% lidocaine or 10 cc. 2% lidocaine.

(b) Infiltration of the different layers

Gently massage anesthetized area to evenly distribute lidocaine. Allow 2-3 minutes for lidocaine to take effect before making the incision. Reserve the remaining lidocaine for anesthetizing individual layers if necessary.

**Entering the Abdomen**

To open and enter the abdomen, the surgeon and the surgical assistant work together.

The main responsibilities of the surgeon are to:

- Incise and dissect the abdominal wall layers
- Access and identify the tubes
- Provide direction to the assistant on how to help

The main responsibilities of the surgical assistant are to:

- Expose the abdominal layers
- Hold the retractors parallel to the client’s abdomen once all layers are opened
- Move the retractors, as needed, to maintain the incision opening
- Actively follow the surgery and help, as needed

Before incising, check for effective anesthesia block in the selected incision site by pinching the skin with a dissecting forceps.

Pull the skin taut to make an incision approximately 2 to 3 cm. long, centered, above the pubic
symphysis. Using a scalpel blade, open an incision only through the epidermis 2 to 3 cm. in length (to a maximum of 5 cm.). The subcutaneous tissue should not be included in the opening of the incision, as it should be dissected bluntly later.

**Entering the abdomen: Opening the skin**

Using a Kelly forceps or the blade of the abdominal retractor (e.g., Richardson-Eastman or Apelo retractors), always working in the midline, bluntly dissect the subcutaneous fat. Do this gently and precisely to minimize tissue trauma and bleeding. Control any bleeding, as needed. Dissect subcutaneous tissue until the anterior rectus fascia is visualized and exposed.

Incise the fascia vertically, using a scalpel at the center of the incision, incise the full thickness of the fascia until the rectus muscle can be seen on both sides of the midline. With the Allis or Kelly forceps, grasp the fascia in the midline of the incision. Free the underlying muscles from the fascia by bluntly dissecting it or by using Mayo scissors.
Entering the abdomen: Grasping the fascia

Note: While two forceps are needed here, only one is shown in the figure for clarity

Entering the abdomen: Dissecting the fascia

Extend the fascial opening vertically on both sides so that it is slightly larger than or about the same length as the skin incision. Have the surgical assistant place the retractors under the fascia and adjust them to expose the linea alba (the midline raphe of the rectus muscle). Retractors should be pulled horizontally to keep the incision open. At this time, one of the forceps can be removed.
Entering the abdomen: Visualizing the muscle layers

![Diagram showing layers of muscle and skin]

Entering the abdomen: Opening the rectus muscle

(a) Separating the rectus muscles

![Diagram showing separation of rectus muscles]
Bluntly separate the rectus muscles vertically at the linea alba, entering through the linea alba with a closed scissors or a hemostat. Once through the linea alba, open the scissors to enlarge the opening. After the rectus muscles are separated, have the surgical assistant reposition the retractors further into the incision, to separate the rectus muscle even more and expose the preperitoneal fat.

**Entering the abdomen: Opening the rectus muscle**

(c) Repositioning the retractors to expose the preperitoneal fat

Entry into the abdominal cavity is safer when the operating table is placed in the Trendelenburg position (with the head of the table tilted downward). This position shifts the bowels out of the operative site, thus minimizing the risk for injury of the bowels. The Trendelenburg position should be less than 20° or
less, to avoid reducing the client’s lung volume and compromising her respiratory ability. To minimize
the length of time the client stays in this position, the tilt is done just before incising the peritoneum and
should return her to the horizontal position as soon after occlusion of the tubes.

**Entering the abdomen: Grasping the peritoneum**

![Diagram of peritoneum](image)

Using the blades of the retractors, bluntly dissect the preperitoneal fat as needed to expose the
peritoneum.

To incise the peritoneum, elevate the peritoneum by grasping it at two points with hemostats. To
prevent injury to the underlying structures, avoid using toothed instruments. Once the peritoneum has
been elevated, to protect underlying viscera and structures from injury, check that the bowels, bladder,
or omentum have not been grasped inadvertently. This should be done once the peritoneum has been
elevated. This is done by using the edge of the scalpel holder to check for translucency and that the
peritoneum has been thinly grasped between the two forceps. Once this has been ascertained, make a
small opening in the peritoneum with scalpel.

Once the peritoneum is open and entry into the abdominal cavity is confirmed, the surgical assistant
should gently reposition the retractors inside the abdomen to maximally expose pelvic structures.
Secure peritoneal edges at one point with forceps then reposition retractors, and assess underlying
tissue for possible injury. From this point until the completion of tubal occlusion, the surgical assistant
must keep the incision open with retractors and must adjust the retractors according to the surgeon’s
needs.

**Accessing and Delivering the Fallopian Tubes**

Accessing and delivering the fallopian tubes requires manipulation of the uterus and the fallopian tubes.
The uterine elevator is the key instrument for moving the uterus and consequently for positioning the
fallopian tubes near the incision area, which allows the surgeon to access them. The process of
manipulating the uterine elevator with one hand and accessing and delivering the tubes with the other
requires coordination.

If the table has not been in Trendelenburgh position yet, the client monitor should do so now.

Elevate the uterus by depressing the uterine elevator as shown in the figure below with one hand. This
will bring the uterine fundus upward toward the incision site. When the uterus is elevated, the retractor
blade bumps on the fundus. Clear the uterus of omentum and bowels which may be obscuring its
visualization.

**Elevating the uterus**

While directly viewing the uterine fundus and keeping the uterine elevator depressed, gently rotate its handle in the opposite direction of the tube being accessed, to position the tube at the incision site. There may be instances when the retractor, as held by the assistant, will have to be gently pulled toward the side of the tube being accessed. As a result of this maneuver, the tube should become visible and can then be grasped.
**Accessing the tubes:** Rotating the uterus to position the right tube at the incision site

When the tube is visualized, grasp the tube atraumatically with baby Babcock or Kelly forceps with the free hand. Keep the uterine elevator in place with the other hand.

**Grasping the tube**

Release the uterine elevator, while holding the tube with forceps. Confirm the identity of the tube by gently pulling it out further and following it to the fimbriated end. It is important to identify the fimbriated end to be certain that the structure held is the tube. This is to avoid the accident that other structures like the round ligament and part of the bowel is ligated which can cause failure and catastrophic complications.
Confirming the identity of the tube

a) Holding the tube while releasing the uterine elevator

b) Pulling the tube further out of the incision

c) Visualizing the fimbrial end of the tube
Occluding the Fallopian Tubes: Pomeroy Technique

At this point, the tube can be ligated.

a) Holding the tubal loop

b) Tying the loop of tube

Place the forceps at the midsection of the tube, in an avascular area, which is about 2-3 cm. from the cornual portion of the tube. Keeping the forceps in a vertical position, hold the loop of tube.

Tie the loop of tube (approximately 2 cm. of tube) with a rapidly absorbable suture like chromic 2-0.

c) Cutting the tube above the knot

d) Checking the stump for bleeding

Cut off 1 cm. of the loop of fallopian tube above the knot using Metzenbaum scissors, leaving at least a 0.5 cm. tubal stump above the knot.

Examine the stump for bleeding.

The steps for visualization of the tube up to this point are repeated for the opposite fallopian tube.
Closing the Abdomen

While grasping both ends of the fascia with forceps and starting at one end of the incision, close the fascia by continuous, interlock sutures with absorbable sutures. Two or three stitches may be needed depending on the length of the incision and the extent of superficial bleeding. Observe for bleeding.

Closing the fascia

![Image: Suture technique for closing the fascia]

The skin may be closed by interrupted or subcuticular continuous stitches using absorbable suture.

Closing the skin

![Image: Suture technique for closing the skin]

Finally, dress the closed incision by swabbing the incision with antiseptic then cover with sterile gauze and plaster.
Dressing the wound

Remove the uterine elevator by gently pulling it out from the vagina.

Place all used instruments in decontaminating solution. Immerse gloved hands in the decontaminating solution then remove them inside out. Put removed gloved in the decontaminating solution.

SUBUMBILICAL MINILAPAROTOMY

Subumbilical minilaparotomy is used for postpartum clients when the uterus is enlarged and easily accessible through a subumbilical approach.

Evaluation of the Client

Ideally, a postpartum client requesting BTL should have been counseled and assessed before arriving at the facility for delivery. Even so, additional counseling and an assessment of her continuing interest in and suitability for sterilization should again be performed before the client is brought to the operating room for the procedure.

An important step is to determine the condition of the infant. In some cases, if the infant’s health is unstable, the client may want to postpone sterilization, since her desire for permanent contraception may change if the infant dies or suffers from some health problem.

Client Preparation Just Before Entering the Operating Room

After the client has been evaluated, the informed consent has been verified, and the decision to proceed with surgery has been made, prepare the client before she enters the operating room, as follows:

- Verify that the client understands the most important steps of the procedure (e.g., what local anesthesia means, what she might feel at various times during the procedure, and that she may be asked to “assist” during the procedure by taking a deep breath).

- Provide a surgical gown for the client and give her a private area in which to change. A client’s modesty should be preserved.

- Ask the client to urinate.

Positioning the Client

Usher the client to the operating room and help unto the operating table. Position the client in the dorsal supine position. The height of the uterine postpartum fundus should be assessed to confirm that it is close to the umbilicus.
Positioning the client for subumbilical minilaparotomy:
Assessing the height of the uterine fundus

Abdominal Preparation

Using an antiseptic-soaked swab on a sponge forceps, clean the umbilicus and throw away the swab. Take a second swab, and starting from the subumbilical area, move progressively out from the umbilicus in circular motion.

Preparing the client's abdominal area before a subumbilical minilaparotomy

Swab at least a 12-cm. circumference progressively in this manner; do not bring the used swab back over the cleaned area.

After allowing the antiseptic to dry, create a sterile field by placing sterile drape sheets around the immediate operative site.

At this moment, the client monitor should administer additional pain medication (e.g., diazepam and meperidine) according to guidelines.

Selecting the Incision Site

The best area for a subumbilical incision is just beneath the umbilicus, as during the immediate
postpartum period the umbilicus is not deep and lies just on top of the enlarged postpartum uterine fundus. Additionally, the abdominal wall in this area is thin and flexible.

**Infiltration of Anesthesia**

Because the abdominal wall at the umbilicus is thin, elevation of the skin and tissues to avoid underlying structures is important. Use tissue forceps to elevate the distal ends of the incision. Infiltrate the skin and fascia with 5-6 ml lidocaine. Gently massage the area to spread the lidocaine. Wait for 2-3 minutes to become effective, test by pinching with toothed tissue forceps prior to making the incision on the skin.

**Entering the Abdomen**

To open and enter the abdomen, the surgeon and the surgical assistant work together with each one having specific responsibilities.

Before incising, check for effective anesthesia block in the selected incision site by pinching the skin with a dissecting forceps.

Make an incision approximately 1.5 to 3 cm. long. Keep skin elevated and on tension with tissue forceps while making the incision. Dissect underlying tissues bluntly and apply retractors until the fascia is visualized.

**The subumbilical minilaparotomy: Incision site**

Identify and elevate fascia with Kelly or mosquito forceps. Make a small incision on the fascia then enlarge transversely.
Entering the abdomen: Visualizing the fascia

If the abdominal cavity has not yet been entered, bluntly strip away any preperitoneal fat and elevate peritoneum with hemostatic forceps. To prevent injury to underlying tissues, check that the bowel, bladder, or omentum has not been grasped inadvertently together with the peritoneum. Before incising the peritoneum, look at the fold of peritoneal tissue that it is translucent and thin.
Entering the abdomen: Opening the peritoneum

Once entry into the abdominal cavity is confirmed, the surgical assistant gently places the blades of the retractors inside the abdomen to maximally expose the uterus and tubes. From this point on until the tubes are occluded, the surgical assistant must keep the incision open with retractors and must adjust the retractors according to the surgeon’s needs.

Accessing and Delivering the Fallopian Tubes

One of the advantages of subumbilical access to the fallopian tubes is that the skin is pliable; this allows the assistant to move the incision to the sides so the tubes can be accessed in the area in which they are located anatomically. Also, the uterus can be manipulated from the outside, allowing the cornua to be moved to the incision and thus making access to the tubes easy.

If the uterus is covered by bowel and/or omentum so that its visualization is obscured, ask the client to take a deep breath while pushing the bowels gently out of the way using the retractors.

Using the retractors to expose the uterus and tubes

Using manual, external pressure on the abdomen, gently push the uterus toward the opposite side of the tube being accessed while the surgical assistant moves the retractors to bring the incision to the corneal area. This will allow visualization of the tube and grasping it.
Accessing the tubes

(a) Pushing the uterus toward the opposite side of the tube being accessed

(b) Moving the incision to be above the tube being accessed

Once the tube has been visualized, grasp it atraumatically with either straight Kelly forceps or baby Babcock forceps. Confirm the identity of the tube by “walking through it” with the forceps to its fimbriated end. At this point, the tube can be ligated.
Grasping and identifying the tube

(a) Grasping the tube

(b) Moving the tube to the opening

(c) Pulling the tube out and visualizing the fimbria
Occluding the Fallopian Tubes: Pomeroy Technique

Place the forceps at the midsection of the tube, in an avascular area, which is about 2-3 cm. from the cornual portion of the tube. Keeping the forceps in a vertical position, hold the loop of tube.

Holding the tubal loop

Tying the loop of tube

Cutting the tube above the knot

Checking the stump for bleeding

Cut off 1 cm. of the loop of fallopian tube above the knot using Metzenbaum scissors, leaving at least a 0.5 cm. tubal stump above the knot.

Examine the stump for bleeding.

The steps for visualization of the tube up to this point are repeated for the opposite fallopian tube.

Close the abdomen and perform succeeding tasks as described for suprapubic minilaparotomy.

HOSPITAL STAY

Clients having an interval procedure should be able to go home the same day. The postpartum procedure and its recovery period do not in themselves add to the usual hospital stay required for a woman who delivers a baby. Sometimes, however, the surgical schedule at the facility may make it necessary for the woman to stay longer.
### PERFORMANCE CHECKLIST ON MINILAPAROTOMY UNDER LOCAL ANESTHESIA

Place a (✓) in case box if step/task is performed **satisfactorily**, an (X) if it is **not** performed **satisfactorily**, or N/O if not observed.

**Satisfactory**: Performs the step or task according to standard procedure or guidelines

**Unsatisfactory**: Does not perform the step or task according to standard procedure or guidelines

**Not Observed**: Step or task not performed by participant during evaluation by trainer

Session 10

POST-OPERATIVE RECOVERY AND DISCHARGE

OVERVIEW

The immediate post-operative recovery period is a critical time because it is at this time that the effects of surgical trauma or other complications first become apparent. Although nurses or other staff members will carry out tasks related to post-operative recovery and discharge, it is essential that the surgeon supervises recovery room care and retains ultimate responsibility for its quality.

This session provides the information needed by the staff to carry a safe and efficient management of post-operative care of clients until discharge.

LEARNING OBJECTIVES

At the end of the session, the participants will be able to:

1. Describe the tasks of the client monitor during the client’s immediate post-operative recovery period.
2. Recognize the signs of post-operative complications.
3. Enumerate the signs of clients’ readiness for discharge.
4. Explain the components of post-operative instructions to clients.

PREPARATION

- PowerPoint slides on “Post-operative Recovery and Discharge”
- Computer and LCD
- Whiteboard and appropriate marker

TIME ALLOTMENT

30 minutes
### Postoperative Recovery and Discharge

#### Learning Objectives

- Describe the tasks of the client monitor during the client’s immediate post-operative recovery period.
- Recognize signs of post-operative complications.
- Enumerate the signs of client’s readiness for discharge.
- Explain the components of post-operative instructions to clients.

#### Postoperative Monitoring

**Postoperative client monitor**

- Keeps track of the client’s recovery from anesthesia and surgery
- Checks and records client’s vital signs every 15 mins. until stabilized at preoperative levels
- Checks the surgical dressing
- Observes the general condition (skin color, postop pain, level of consciousness, orientation to time and space)
- Administers drugs and treatment for pain, as instructed by the surgeon
- For interval cases
  - Checks for vaginal bleeding other than menstruation. If bleeding, refers to surgeon.
  - Records data pertaining to recovery period

#### Signs of Postoperative Complications

- Inability to retain fluids (vomiting)
- Inability to urinate
- Inability to ambulate (unsteady when standing)
- Signs of hypovolemia (feels like fainting upon rising, rapid pulse, unable to void)
- Excessive somnolence
- Respiratory rate < 10/min
- Hyperventilation
- Systolic BP < 90mmHg
- Weak pulse
- Pallor
- Cyanosis

---

**Introduction**

Introduce the session by providing an “Overview” for the topic.

**State the “Learning Objectives” of the session as presented on PowerPoint slides.**

**Describe the tasks of the client monitor during the post-operative period as presented on the slide.**

**Elicit additional ideas, questions, and comments from participants.**

**Enumerate the signs of post-operative complications as presented on the slide.**
Readiness for Discharge

Signs of readiness for discharge
- Must be able to take fluids and retain it
- Able to urinate
- Walks upright with minimal support
- Vital signs at preoperative levels
- No signs of bleeding (no undue vaginal bleeding, pulse and BP normal)
- Wound is not bleeding

Enumerate the signs of the client’s readiness for discharge as presented on the slide.

Postoperative Instructions

Staff provides client with oral and written instructions
- When and where to return for follow-up
- Take paracetamol for pain
- How to care for the wound
- Side effects
- What to do for signs of complications
- When to resume normal activities

Enumerate the content of post-operative instructions as presented on the slide.

Emphasize that these instructions must be explained to the clients verbally and must be written.

Sample Post-operative Instructions

Show a sample of a written post-operative instruction form.

Tell participants that:
- The post-operative instructions must be written in the dialect that the client understands.

Conclusion

Review the objectives.

Ask questions to check participants’ understanding of the topics.
POST-OPERATIVE MONITORING

In the post-operative period, staff observes the client constantly. The post-operative client monitor (this may be the same staff member responsible for intraoperative monitoring) receives the client from the operating room and reviews the client record. When moving the client, the monitor handles her gently; making sure the client is comfortable while in the recovery area.

The post-operative client monitor keeps track of the client's recovery from the anesthesia and the surgery. The monitor checks and records the client's vital signs - blood pressure, respiration, and pulse - every 15 minutes until they are stabilized at preoperative levels, then as necessary until client has fully recovered from the effects of anesthetics.

For interval cases, the post-operative client monitor checks for vaginal bleeding other than menstruation. If the client is bleeding, the monitor informs the surgeon who checks for injury to the cervix or uterus caused by the uterine tenaculum. The monitor checks the surgical dressing for oozing or bleeding and observes the general condition of the client (including monitoring changes in skin color, post-operative pain, level of consciousness, and orientation to time and space).

The monitor administers drugs and treatment for pain and other symptoms according to the surgeon's orders and provides bland carbohydrates and liquids to raise blood sugar levels. All data pertaining to the recovery period are recorded on the client's chart.

DETERMINING CLIENT READINESS FOR DISCHARGE

Sometimes a client is not ready for discharge and may even require overnight observation following surgery. If she is unable to retain fluids (is vomiting) or is unable to ambulate (is unsteady when standing), then she is not ready for discharge.

If she shows signs of hypovolemia, such as the inability to void, dizziness, or increased pulse rate when going from lying to sitting or standing, she should be rehydrated and observed. (An increase in the pulse when going from a lying to a sitting position with legs dangling is a more sensitive indicator of hypovolemia than is low blood pressure.) If these symptoms worsen, the monitor must inform the surgeon because of the possibility of intra-abdominal hemorrhage.

An incomplete recovery from sedation or anesthesia is another indication that the client is not ready for discharge. If she does not recover in time to arrive home at a reasonable hour, then she should not be discharged. She should also remain at the facility if no responsible adult is available to accompany or transport her home.

Only after sufficient recovery is the client allowed to be discharged. She must be able to take fluids and light nourishment and retain them. She needs to walk upright with minimal support. If she is perspiring, it must be only for reasons related to climate. Her vital signs must be at preoperative levels. The wound must show no bleeding or seepage.

As a prerequisite to discharge, staff must ensure that the client knows the signs of complications to watch out for and understands specific instructions, including:
• That she should return to the clinic immediately or seek emergency care if a problem develops.
• The post-operative instructions and be able to repeat them, including the date of scheduled follow-up.
• How to obtain any home medications that have been ordered.

Finally, the operating surgeon or his or her designee must confirm that the client is ready for discharge. The client should then be provided with written post-operative instructions.

**POST-OPERATIVE INSTRUCTIONS**

Before discharge, a staff member gives the client written post-operative instructions and asks her to repeat them, gives her a follow-up appointment, and confirms that she is ready for discharge. Clients should also be advised to take paracetamol or another safe locally available pain reliever as needed. (The surgeon or his/her designee performs this last task.)

Post-operative instructions to the client may vary depending on the facility and the client.

However, basic information must be addressed. The client must know how to care for the wound. She should know which symptoms are normal side effects of the procedure and which are signs of complications, indicating that she should return to the clinic. In emergencies, she must be able to contact the proper personnel and go to the appropriate place. She needs to know when it is safe to resume normal activities, including sexual relations. Finally, she needs to understand the importance of a follow-up visit and when and where to go for it.

Written post-operative instructions should be given to all clients for discharge, if an illiterate client is unable to read them, she can usually find a literate person to read them for her.

**REST AFTER SURGERY**

The healthy client having an interval procedure should be able to return to completely normal activities within seven days after surgery. For healthy women who undergo minilaparotomy immediately after delivery of a child, the procedure should not extend the normal postpartum hospitalization. For example, in hospitals where women are discharged within 24 hours following a normal vaginal delivery, an uncomplicated postpartum minilaparotomy done within that period of time should not require extended hospitalization.
SAMPLE POST-OPERATIVE INSTRUCTIONS

1. Avoid physical work and strenuous exercise for at least one week to allow the abdominal incision to heal. Resume normal activities after two or three days.

2. Take prescribed simple analgesic every 4-6 hours for relief of pain or discomfort.

3. Keep the incision site (wound) clean and dry.
   Steps in Cleaning:
   a. Clean with hydrogen peroxide and dry
   b. Apply antiseptic solution – Betadine
   c. Cover with sterile or clean gauze (OS)
   d. Apply plaster

4. Bathing should be 1 day after surgery. When you bathe, keep the incision site dry. Avoid pulling, rubbing or otherwise irritating the incision site.

5. If the suture is absorbable tell the patient that the stitches will dissolve by themselves, however, if non-absorbable sutures such as silk patient should come back 5-7 days after surgery for removal.

6. Pain at the incision site is a normal symptom after the surgery.

7. Consult the doctor or health workers immediately if you have the following symptoms which are danger signals
   • fever
   • abdominal pain that is persistent or increasing
   • bleeding or pus from the incision site
   • suspected pregnancy (missed period) especially if accompanied by vaginal bleeding or pain at any time in the future.

7. Sexual intercourse should be avoided one (1) week after surgery.

8. Return to the facility for a follow-up visit on ____________________________.

PRINTED NAME AND SIGNATURE
(Doctor, Nurse or Midwife)
MGA TAGUBILIN PAGKATAPOS NG OPERASYON

1. Iwasan ang pisikal na gawain at ehersisyong mabigat nang mga isang linggo upang maghilom ang hiwa sa tiyan. Ipapatuloy ang normal na gawain pagkaraan ng dalawo o tatlong araw.

2. Uminom ng iniresetang gamot (analgesic) tuwing 4-6 na oras para maalis ang sakit o hirap.

3. Panatilihing malinis at tuyo ang hiwa (sugat).
   Paraan ng paglilinis:
   a. Gumamit ng hydrogen peroxide at punasan.
   b. Lagyan ng antiseptic solution – Betadine.
   c. Takpan ng esterilesado o malinis na gasa (OS).
   d. Lagyan ng plaster.

6. Ang pananakit at pagkirot sa lugar ng hiwa ay normal na palatandaan pagkatapos ng patitistis.

7. Kumunsulta agad sa doktor o mga katulong sa panggagamot kung isa sa mga sumusunod ay mapansin. Ito ay maaring hudyat ng panganib:
   • lagnat
   • matinding sakit ng tiyan
   • pagdurugo o nana mula sa lugar ng hiwa
   • pamamaga sa lugar ng hiwa
   • hindi dinadatnan ng buwanang dalaw – lalo na kung dinudugo o sumasakit ang tiyan.

8. Hindi dapat magtalik ng mga isang (1) linggo pagkatapos ng pagtitistis.

9. Bumalik para sa susunod na pagkunsulta sa _______________________.

______________________________
PANGALAN AT LAGDA (limbag)
(Doktor, Nars o Kumadrona)
TRANSFER OF CLIENT RECORDS

All of the client's records should be maintained at the site where the procedure took place. If the follow-up will take place at another facility, the client should receive a card to give to the follow-up provider, indicating the date of procedure, the type of procedure, and any special instructions. If it is necessary to transfer a copy of the client's records, the original should be kept at the facility where the surgery took place, to facilitate program evaluation.

SIGNS OF POSTOPERATIVE COMPLICATIONS

Staff must also be alert to complications, which may be signaled by:

- Inability to retain fluids (vomiting)
- Inability to urinate
- Inability to ambulate (client is unsteady when standing)
- Signs of hypovolemia (client feels like fainting upon rising, has rapid heart rate, is unable to void)
- Excessive somnolence
- Breathing rate of less than 10 respirations (breaths) per minute
- Hyperventilation
- Systolic blood pressure of less than 90 mm. mercury
- Rapid pulse rate (over 90 beats per minute)
- Weak pulse
- Pallor
- Perioral cyanosis

Whenever a complication is suspected, the surgeon must be informed and must evaluate the client. If the surgeon feels the client requires treatment at another facility, s/he must make those arrangements.
Session 11

MANAGEMENT OF COMPLICATIONS

OVERVIEW

Programs must ensure the safety of women undergoing ML/LA. Surgeons must be trained and skilled in the techniques they are using, in the use of appropriate and safe anesthesia, in the proper use of a uterine elevator, in emergency abdominal surgery, in identifying complications should these occur, and in other procedures for managing emergencies. Minilaparotomy clients do not die of complications, but they can die of "complications of a complication.

This session provides the necessary information in preventing, identifying, and managing complications.

LEARNING OBJECTIVES

At the end of the session, the participants will be able to:

1. State the main causes of complications of BTL/MLLA.
2. Discuss the anesthesia-related complications as to the:
   - Possible complications
   - Signs of complication
   - Contributing factors to complications
   - Management
3. Discuss surgical injuries which causes complications as to their:
   - Prevention
   - Types of incurred during surgery
4. Discuss important issues related to:
   - Pregnancy
   - Death

PREPARATION

- PowerPoint slides on “Management of Complications”
- Computer and LCD
- Whiteboard and appropriate marker
- Case studies
- Sheets of paper with a case
- Easel sheets and markers
TIME ALLOTMENT

1 hour and 30 minutes

REFERENCES

### Minilaparotomy clients do not die of complications, but they can die of "complications of a complication."

### Learning Objectives

1. State the main causes of complications of ML-LA.
2. Discuss the anesthesia-related complications as to the:
   - Possible complications
   - Signs of complication
   - Contributing factors to complications
   - Management
3. Discuss surgical injuries which causes complications as to their:
   - Prevention
   - Types of incurred during surgery
4. Discuss important issues related to:
   - Pregnancy
   - Death
1. **Anesthesia Complications**
2. **Surgical Complications**

Present the two common types of complications which may occur when performing BTL/MLLA as written on the slide.

**Discuss the possible complications of BTL/MLLA as presented on the slides.**

---

**Anesthesia-Related Complications**

- **Possible Complications**
  - Respiratory depression or arrest
  - Cardiovascular changes, including arrhythmia, hypotension, or hypertension
  - Cardiac arrest
  - Convulsions
  - Aspiration of vomitus

- **Signs**
  - Decreased breathing rate
  - Short, shallow, quick breathing
  - Dyspnea, gasping, laryngeal stridor
  - Peribuccal cyanosis (blueness around the mouth)
  - Cyanotic nail beds (bluish fingernail beds)
  - Irregular or rapid pulse
Signs

- Central nervous system changes (restlessness, anxiety, and disorientation)
- Convulsions or loss of consciousness
- Hypotension
- Absence of pulse, heart sounds, respiration, reflexes, and muscle tone

Contributory Factors

- Overdose of analgesic
- Overdose of sedative or tranquilizer
- Combined effect of drugs
- Delayed effect (drugs reaching their peak of effectiveness after monitoring has been relaxed)

Contributory Factors

- Intravascular injection of lidocaine
- Overdose of lidocaine
- Pre-existing cardiac disease
- Severe blood loss with intravascular volume depletion

Management

Cardio-respiratory arrest
- Start resuscitation (CPR)
- Sodium bicarbonate of 1 mmol/kg B.W. (8.4%=1mmol/ml)
- Epinephrine of 0.1-0.5 mg. IV for asystole
- Atropine of 1 mg. IV for bradycardia
Management

Drug overdose

– Naloxone (narcotic antidote)
– Physostigmine or Flumazenil (benzodiazepine antidote)

Preventing Surgical Complications

• Routinely have the client empty her bladder just before surgery
• Examine a fold of the peritoneum before incising
• Perform the surgery gently
• Use non-toothed instruments to grasp intra-abdominal tissue.

2. Surgical Trauma

Preventing Surgical Complications

• Expose the fimbrial end of the tube to confirm identification.
• Apply ligatures carefully and correctly.
• Inspect the tissues thoroughly before closing the incision, to make sure there is no bleeding.
• Strict adherence to infection prevention practices.
Preventing Surgical Complications

Postpartum Procedures

- Do not use a uterine elevator
- Perform surgery gently to avoid trauma to the uterus and fallopian tubes
- Perform surgery within 48 hours up to 7 days from delivery

Preventing Surgical Complications

Postpartum Procedures

- Rule out any condition that would increase the risk of infection or complications from anesthesia (e.g., suspected infection during labor and delivery, hemorrhage, pulmonary and cardiac problems)
- Use caution in making the incision in the thin abdominal wall near the umbilicus, so as not to cut the structures underneath.

Preventing Surgical Complications

Interval Procedures

- Insert the uterine elevator properly and manipulate gently to avoid perforating the uterus
- Test for mobility or presence of pain.

Bladder Injury

Signs

- Intraoperatively
  - Clear fluid welling up into the operative site
  - Rugal folds of the bladder mucosa
- Postoperatively
  - Hematuria
  - Suprapubic pain
  - Fever or signs of infection
Bladder Injury

Contributory Factors
– Failure to ensure bladder was emptied before surgery
– Inappropriate location of the incision
– Failure to check for translucence of the grasped peritoneal fold before incising

Bladder Injury

Management
• Insert an indwelling (Foley) catheter.
• If bladder injury is suspected, instill a sterile solution (methylene blue, gentian violet, sterile water or milk, or intravenous solution) into the bladder through the catheter.
• Repair the injury in two layers, using continuous suture of fine catgut with an atraumatic needle.

• Continue the tubal occlusion procedure if the injury is minor.
• Initiate a course of antibiotics.
• Hospitalize if the injury is extensive.
• Remove the catheter seven days later and monitor for ability to void.

Bowel Injury

Signs
• Intraoperatively
  – Visualization of bowel serosa or muscularis
  – Visualization of bowel contents
• Postoperatively
  – Abdominal pain that increases in severity
  – Vomiting
  – Failure to pass flatus
  – Abdominal distension
  – Abdominal tenderness
**Bowel Injury**

**Contributory Factors**
- Failure to feel the grasped fold of peritoneum to ensure bowel is not adherent to it before opening.
- Failure to look for translucence of the tissue fold before opening
- Quick and deep entry through the thin abdominal wall at the umbilicus during postpartum procedures

**Bowel Injury**

**Treatment**
- Promptly repair the defect with fine silk suture in multiple layers, using an atraumatic needle.
- If the injury is superficial (serosal layer only):
  - allow the client to rest an extra hour
  - discharge with instructions to return immediately if pain or fever begins
  - make arrangements for follow-up of client in the next 48 hours.
- If the injury is through to the bowel lumen:
  - initiate intravenous antibiotics and hospitalize the client for observation following the repair
- If fecal matter is expelled into the abdomen:
  - lavage the peritoneal cavity with sterile solution
- Complete the tubal occlusion procedure after repairing the bowel.

**Uterine Perforation**

**Signs**
- Tip of elevator seen protruding through the uterine wall
- Inability to elevate the uterus against the abdominal wall
- Superficial palpation of the tip through the abdominal wall
- Metallic sound of the tip against the abdominal retractors
- Bleeding
**Uterine Perforation**

**Contributory Factors**
- Improper insertion of the uterine elevator
- Rough manipulation of the uterine elevator
- Postpartum uterus that is still soft (even at six weeks)

**Treatment**
- If the uterus is anteverted, consider leaving the elevator in place while the tubes are occluded, using extreme gentleness if the uterus is manipulated.
- If the uterus is retroverted, consider repositioning the elevator, rotating the elevator to an anteverted position, and then occluding the tubes.

**Uterine Perforation**

**Treatment**
- After the tubes are occluded, remove the elevator and examine the perforation site for bleeding (usually only a slight oozing).
- If fresh bleeding occurs, control it with a “figure of 8” suture, using catgut (preferably chromic catgut).

**Uterine Perforation**

**Treatment**
- If bleeding has been controlled, close the abdomen and observe the client for an extra one to two hours.
- *Initiate a course of antibiotics*
- Consider hospitalization if continuous bleeding is suspected or if posterior perforation with vessel injury occurred.

**Case Studies**

Ask participants to pair.
Provide each pair of participants a case study. The pair discusses the case and answer the following questions (answers are written on easel sheets):

- What is the problem/complication?
- What are the signs that point to the problem?
- What factor/s caused the problem?
- How is the problem managed?

Plenary:
Each case is presented in plenary.

Members of other groups comment/ supplement to the discussed case.

Supplement further... making sure areas mentioned in the answer key are all covered in the discussions for each case study.

Summary:

- Ask participants what they have learned from the case studies.
- Close the exercise by saying that:
  - With careful surgery that is in accordance with protocols, complications are prevented.
  - If complications happen, it is important that the complication is immediately identified and managed because clients do not die from complications but from complications of complications.

Discuss the issues on failure (pregnancy) and death as presented on the slides.

**Pregnancy**

**Important Issues**

- Staff should be prepared to manage pregnancies that occur after sterilization surgery, or to refer clients appropriately.
- Clients should understand that failure is a possibility and should immediately consult if they have any symptoms of pregnancy.
- Ectopic pregnancy must be considered.
- Cause of failure should be investigated.
Pregnancy

**Signs of Ectopic Pregnancy**

- Sudden intense pain, persistent pain, or cramping in the lower abdomen, initially then becoming generalized.
- Irregular bleeding or spotting with abdominal pain after a missed or abnormally light menstrual period.
- Fainting or dizziness that is associated with either of the above conditions and that persists for more than a few seconds (which could indicate internal bleeding).

Death

**Analyze the cause:**

- The immediate and contributing causes
- Whether the death was attributable to the minilaparotomy procedure
- Whether the death was attributable to the anesthesia regimen
- Whether staff could have anticipated or prevented any of the factors in the death
- Corrective measures to prevent occurrence of a similar death

Conclusion

Review the learning objectives of the session. Ask questions and call on participants at random.
CASE STUDIES (with answer key)

1. Ten minutes after IV administration of Meperidine 50 mg. and Diazepam 10 mg., client was still noted to be awake. The surgeon ordered additional of 25 mg. Meperidine and 5 mg. Diazepam by slow IV. A few minutes after administration of these additional medications, client was noted to have shallow, rapid breathing with beginning peribuccal cyanosis.

   Problem: overdose/accumulated effect of narcotic analgesic (Meperidine) and sedative (Diazepam)
   Signs: shallow, rapid breathing, peribuccal cyanosis
   Cause/s: additional administration of analgesic and sedative; fast or bolus administration of analgesic and sedative
   Management: O2 inhalation
               Naloxone
               Physostigmine

2. After infiltration of the operative site with Lidocaine 2%, client went into convulsive seizures.

   Problem: Lidocaine toxicity
   Signs: convulsive seizure after Lidocaine administration
   Cause/s: inadvertent intravenous administration of Lidocaine caused by not ensuring that a vein was hit prior to administration (not aspirating prior to administration)
   Management: early recognition of the symptoms of lidocaine toxicity with aggressive management is important to prevent cardiac complications (arrhythmia and arrest)
               O2 inhalation
               Diazepam to control seizures
               Sodium bicarbonate to prevent acidosis which can potentiate cardiac arrest

3. Upon opening the abdomen of a postpartum client, a gush of urine-smelling fluid was noted.

   Problem: bladder was perforated
   Signs: gush of urine-smelling fluid
   Cause/s: failure to ensure that the bladder was emptied before surgery; quick and deep entry through the thin abdominal layer at the periumbilical area where the fascia and peritoneum are closely apposed; failure to check for translucence of the peritoneal fold before incising
   Management: insert a foley catheter; repair the injury in two layers, using continuous suture of fine catgut with an atraumatic needle; confine client and monitor urine output for absence of hematuria and ability to urinate; keep foley catheter in place for seven days; provide antibiotics.
4. Post-minilaparotomy client had an uneventful operative course until 24 hours after the procedure when she comes back to the clinic complaining of vomiting with severe abdominal pain and distention. On examination, client was febrile and the abdomen was noted to be rigidly distended, tender, and absent bowel sounds on auscultation.

   **Problem:** bowel perforation

   **Signs:** rigid, tender abdomen, absent bowel sounds, fever

   **Cause/s:** failure to look for translucence and feel the grasped fold of peritoneum to ensure that the bowel was not adherent to the peritoneum

   **Management:** re-open the abdomen and repair the defect with fine silk suture in multiple layers, using an atraumatic needle; lavage the abdominal cavity with sterile saline solution to clean it of fecal material; administer antibiotics; confine the client for observation

5. Post-minilaparotomy client had an uneventful operative course until 24 hours after the procedure when she comes back to the clinic complaining of abdominal pain and a large bluish, red mass beneath the skin and the dressing soaked in blood. On examination, the incision wound was oozing with blood and a bluish, red mass was noted on the abdominal wall.

   **Problem:** hematoma

   **Signs:** bleeding from the site of incision, mass in the abdominal wall

   **Cause/s:** failure to ensure hemostasis; bleeders in the subcutaneous area were not ligated

   **Management:** re-open the abdomen to determine the site of bleeding, evacuate blood clots and ligate the bleeders; provide antibiotics; arrange for consultation the next day to check the dressing and ensure that bleeding is controlled
GUIDING PRINCIPLES

Surgical complications can and do occur even when staff has taken appropriate preventive measures. Early recognition and treatment of complications are essential.

 Experienced doctors have said that, in the case of minilaparotomy under local anesthesia, clients do not die of complications, but they can die of "complications of a complication." In other words, the persons involved in recognizing or treating the complication did something that made the complication worse, or failed to do something that might have relieved the condition.

 All members of a surgical team, not just the doctor, are responsible for identification and management of complications. Proper and prompt management of a complication protects the health and perhaps the life of the client, protects the staff, protects the program, and protects the reputation of the procedure.

 Because an anesthetist is not usually present when minilaparotomy is done under local anesthesia, the doctor and the other surgical team members must know how to identify and manage complications related to sedatives and narcotics.

 Some complications associated with minilaparotomy are not recognizable until after the client is discharged from the facility. The staff working in the follow-up clinic should have the capability of identifying signs of complications such as wound or pelvic infection, peritonitis resulting from an unrecognized bowel injury, and pregnancy. The staff should be able to report these late complications and manage them or make referrals for their management.

 One of the primary goals of training in minilaparotomy is to teach techniques and skills that will keep complications to a minimum. Prevention must be stressed throughout training courses and during service delivery.

 By using the proper and cautious surgical techniques and follow-up staff can prevent complications related to surgical trauma.

 Many of the complications potentially associated with minilaparotomy are common to general abdominal surgery, and their management is dependent upon general surgical knowledge and skills. Such complications include vasovagal syncope, hemorrhage, wound infection, and aspiration of gastric contents. Because most providers have confronted these complications in their surgical practices, this chapter does not address them.

 DEFINITION OF TERMS

 A side effect is a consequence of the procedure that does not require exceptional intervention. (e.g., abdominal cramping)

 A complication is an abnormal condition caused by the procedure that requires intervention or management beyond what was planned. (A wound infection noted on the fifth day after surgery that requires incision and drainage is an example of a complication.)
PREVENTING COMPLICATIONS OF MINILAPAROTOMY

For both postpartum and interval procedures, the surgeon should take the following steps to minimize complications:

1. Routinely have the client empty her bladder just before surgery, to avoid incising the bladder.
2. Examine a fold of the peritoneum before incising, to ensure that nothing is adherent below.
3. Perform the surgery gently, to prevent tearing and bleeding of the fallopian tubes and mesosalpinx.
4. Use a non-toothed instrument, such as a straight artery forceps (Kelly) or a baby Babcock to grasp intra-abdominal tissue.
5. Expose the fimbrial end of the tube to confirm identification.
6. Apply ligatures or clips carefully and correctly.
7. Inspect the tissues thoroughly before closing the incision, to make sure there is no bleeding.
8. Strict adherence to infection prevention practices.

Postpartum Procedures

For postpartum procedures, the surgeon should take the following steps to minimize complications:

- Do not use a uterine elevator.
- Perform surgery gently to avoid trauma to the uterus and fallopian tubes.
- Perform surgery within 48 hours of delivery.
- Rule out any condition that would increase the risk of infection or complications from anesthesia. Infection is an indication for postponement after vaginal delivery; other such indications are intrapartum or postpartum hemorrhage resulting in severe anemia, and pulmonary or cardiac problems.
- Use caution in making the incision in the thin abdominal wall near the umbilicus, so as not to cut the structures underneath.

Interval Procedures

For interval procedures, the doctor should take the following steps to minimize complications:

- Insert the uterine elevator properly and manipulate gently to avoid perforating the uterus while also testing for mobility or presence of pain.

IMMEDIATE ACTION REQUIRED

In addition to taking the specific emergency measures detailed throughout this chapter, surgical staff should do the following when a complication arises:

- Discontinue the minilap procedure while emergency treatment is under way and may resume/complete the procedure, when client’s condition has stabilized.
- Return a Trendelenburg table to the horizontal position.
• Complete the surgery only if the client's condition has stabilized.
• Consider hospitalizing the client for observation.
• Record the complication and the treatment rendered.

ANESTHESIA COMPLICATIONS

Complications Related to the Anesthesia Regimen
• Respiratory depression or arrest
• Cardiovascular changes, including arrhythmia, hypotension, or hypertension
• Cardiac arrest
• Convulsions
• Aspiration of vomitus

Signs of Anesthesia-Related Complications
• Decreased breathing rate
• Short, shallow, quick breathing
• Dyspnea, gasping, laryngeal stridor
• Peribuccal cyanosis (blueness around the mouth)
• Cyanotic nail beds (bluish fingernail beds)
• Irregular or rapid pulse
• Central nervous system changes (restlessness, anxiety, and disorientation)
• Convulsions or loss of consciousness
• Hypotension
• Absence of pulse, heart sounds, respiration, reflexes, and muscle tone

Factors
• Overdose of analgesic
• Overdose of sedative or tranquilizer
• Combined effect of drugs
• Delayed effect (drugs reaching their peak of effectiveness after monitoring has been relaxed)
• Intravascular injection of lidocaine
• Overdose of lidocaine (which may be a result of use of an undiluted 2% solution)
• Pre-existing cardiac disease
• Severe blood loss with intravascular volume depletion

The above factors themselves may have a variety of causes:

• Staff may fail to recognize signs of an overdose.
• The client monitor may be distracted by other duties.
• Staff may lack knowledge of medicines used in the procedure.
• Emergency equipment may be unavailable or nonfunctioning.
• Staff may lack skills in the use of emergency equipment.
• Antidotes (naloxone, physostigmine, flumazenil) may not be available.
• Staff may be unclear about their roles and responsibilities for taking action when the doctor is absent or before the doctor arrives.

MANAGEMENT OF COMPLICATIONS

Cardio-respiratory Arrest

Treatment of cardio-respiratory arrest is extremely urgent; irreversible brain damage will occur if the oxygen supply to the brain is cut off for more than three minutes. It is possible to maintain the circulation and ventilation of the lungs by active resuscitation while the underlying cause of the arrest is treated, and many persons recover well after such treatment.

When faced with a collapsed client, staff should first check the airway, breathing, and circulation (this takes about 15 seconds). Upon recognition of cardio-respiratory arrest, the following should be done immediately:

• Start resuscitation and do not leave the client. Request for immediate assistance.
• Clear the airway and inflate the lungs by whatever means are available: the resuscitator’s own expired (by mouth-to-mouth) air, a bag or bellows, or oxygen.
• If the client has no major pulse, start external cardiac massage. With one hand on top of the other, staff should press sharply down on the lower third of the sternum in the midline; this compresses and empties the heart between the sternum and vertebral column. A massage rate of 60 compressions per minute is appropriate. After every four compressions, inflate the lungs once; watch the chest rise and fall with each inflation.
• When possible, look at the client’s pupils. Small pupils indicate effective resuscitation; fixed, dilated pupils may indicate brain damage from hypoxia. If the pupils are initially large, but then become smaller, the resuscitative efforts are succeeding.
• When help is available, set up an intravenous infusion while maintaining ventilation and massage, and give sodium bicarbonate in a dose of 1 mmol./kg. of body weight (an 8.4% sodium bicarbonate solution contains 1 mmol./ml.).
• Obtain an electrocardiogram to confirm that the cardiac rhythm has been reestablished, and treat any dysrhythmias.
Investigate the cause of the cardiac arrest and try to determine why it happened when it did. Consider possibilities such as the following:

- Hypoxia
- Drug overdose
- Allergic reaction
- Myocardial infarction
- Pulmonary embolism
- Hypovolemia
- Disturbance of electrolytes (specially potassium)

Treat the underlying cause of the arrest once it is identified.

Consider using the following drugs for immediate management:

- Calcium gluconate for poor myocardial function and short-term protection against hyperkalemia, up to 1 g. intravenously
- Epinephrine, 0.5 mg. subcutaneously for allergic reactions; 0.1–0.5 mg. intravenously for asystole (confirmed by electrocardiogram, or if there is no cardiac output in spite of an acceptable heart rhythm)
- Atropine, 1 mg intravenously for bradycardia

If resuscitation is successful, staff should ensure that the client continues to receive treatment for the underlying cause of the cardiac arrest. Staff should maintain a safe airway after the client starts to breathe spontaneously again. The endotracheal tube should stay in place until the client has regained consciousness and protective reflexes.

**Drugs Used to Treat Anesthesia-Related Complications**

**For drug overdose**

- Narcotic antidote (naloxone)
- Benzodiazepine antidote (physostigmine or flumazenil)

**For cardiac arrest** (only used during assisted respiration and cardiac resuscitation)

- Epinephrine
- Lidocaine
- Sodium bicarbonate solution
- Calcium chloride
Surgical Trauma

Complications Related to the Surgical Procedure

- Injury to the bladder
- Injury to the bowel
- Injury to the uterus
- Uterine perforation
- Injury to the fallopian tube
- Injury to blood vessels causing bleeding

Bladder Injury

Signs of Bladder Injury

- Intraoperatively
  - Clear fluid welling up into the incision or operative site
  - Sight of the rugal folds of the bladder mucosa
- Postoperatively
  - Hematuria
  - Suprapubic pain
  - Fever or signs of infection

Contributory Factors

- Failure to ensure bladder was emptied before surgery
- Inappropriate location of the incision
- Failure to check for translucence of the grasped fold before incising

Treatment of Bladder Injury

- Insert an indwelling (Foley) catheter.
- If bladder injury is suspected, instill a sterile solution (methylene blue, gentian violet, sterile water or milk, or intravenous solution) into the bladder through the catheter.
- Repair the injury in two layers, using continuous suture of fine catgut with an atraumatic needle.
- Continue the tubal occlusion procedure if the injury is minor.
- Initiate a course of antibiotics.
- Hospitalize if the injury is extensive.
- Remove the catheter seven days later and monitor for ability to void.

**Bowel Injury**

**Signs of Bowel Injury**

- Intraoperatively
  - Visualization of bowel serosa or muscularis
  - Visualization of bowel contents
- Postoperatively
  - Abdominal pain that increases in severity
  - Vomiting
  - Failure to pass flatus
  - Abdominal distension
  - Abdominal tenderness

**Contributory Factors**

- Failure to feel the grasped fold of peritoneum to ensure bowel is not adherent to it before opening.
- Failure to look for translucence of the tissue fold before opening
- Quick and deep entry through the thin abdominal wall at the umbilicus during postpartum procedures

**Treatment of Bowel Injury**

- Promptly repair the defect with fine silk suture in multiple layers, using an atraumatic needle.
- If the injury is superficial (serosal layer only), allow the client to rest an extra hour, then discharge with instructions to return immediately if pain or fever begins. Make arrangements for follow-up of client in order to monitor any change in condition over the next 48 hours.
- If the injury is through to the bowel lumen, initiate intravenous antibiotics and hospitalize the client for observation following the repair.
- If fecal matter is expelled into the abdomen, lavage the peritoneal cavity with sterile solution (for example, normal saline).
- Complete the tubal occlusion procedure after repairing the bowel.

**Uterine Perforation**

**Signs of Uterine Perforation**

- Tip of elevator seen protruding through the uterine wall.
- Inability to elevate the uterus against the abdominal wall
• Superficial palpation of the tip through the abdominal wall
• Metallic sound of the tip against the abdominal retractors
• Bleeding

**Contributory Factors**

• Improper insertion of the uterine elevator
• Rough manipulation of the uterine elevator
• Postpartum uterus that is still soft (even at six weeks)

**Treatment of Fundal Uterine Perforation**

• If the uterus is anteverted, consider leaving the elevator in place while the tubes are occluded, using extreme gentleness if the uterus is manipulated.
• If the uterus is retroverted, consider repositioning the elevator, rotating the elevator to an antverted position, and then occluding the tubes.
• After the tubes are occluded, remove the elevator and examine the perforation site for bleeding (usually only a slight oozing).
• If fresh bleeding occurs, control it with a “figure of 8” suture, using catgut (preferably chromic catgut).
• If bleeding has been controlled, close the abdomen and observe the client for an extra one to two hours.

**Initiate a course of antibiotics**

• Consider hospitalization if continuous bleeding is suspected or if posterior perforation with vessel injury occurred.

**Pregnancy or Failure**

Pregnancy can occur immediately after minilaparotomy or many years later. Two types of pregnancies can occur after minilaparotomy: intrauterine and ectopic. The signs and management of pregnancy following minilaparotomy are the same as for any other pregnancy.

Four issues are of particular importance:

• Staff should be prepared to manage pregnancies that occur after sterilization surgery, or to refer clients appropriately.
• Supervisors or managers need to review the signs/symptoms and management of ectopic pregnancy with staff working in follow-up clinics.
• Staff must be sure that clients understand that failure is a possibility and that they should go to a health care facility if they have any symptom of pregnancy. This is especially important because ectopic pregnancy is potentially life threatening.
• Health care workers in the field must know that pregnancy is a possible complication and must advise clients to go to a health facility if they think they may be pregnant.
**Signs of Ectopic Pregnancy**

- Sudden intense pain, persistent pain, or cramping in the lower abdomen, initially then becoming generalized.
- Irregular bleeding or spotting with abdominal pain after a missed or abnormally light menstrual period.
- Fainting or dizziness that is associated with either of the above conditions and that persists for more than a few seconds (which could indicate internal bleeding).

**Death**

Worldwide experience has shown that deaths associated with minilaparotomy are very rare (5.1/100,000 from 1982 to 1988). Because minilaparotomy under local anesthesia is an elective procedure that usually carries very little risk to the client, program managers must carefully analyze every death to determine the following:

- The immediate and contributing causes
- Whether the death was attributable to the minilaparotomy procedure
- Whether the death was attributable to the anesthesia regimen
- Whether staff could have anticipated or prevented any of the factors in the death
- Corrective measures to prevent occurrence of a similar death
Session 12

FOLLOW-UP

OVERVIEW

The post-operative follow-up is an opportunity to assess clients’ reaction to the BTL/MLLA procedure performed on her. It is the time to determine any surgical problems and to respond to clients’ additional concern on the use of the method and its permanence. These are important reasons for a follow-up visit to be scheduled a week after surgery in a facility convenient to the clients and with staff that are knowledgeable on conducting this.

This session provides the necessary information on doing post-BTL/MLLA follow-up.

LEARNING OBJECTIVES

At the end of the session, the participants will be able to:

1. Describe the two kinds of follow-ups for post-BTL/MLLA clients.
2. Discuss the components of routine and emergency follow-ups.
3. Explain what to do for failure of tubal occlusion resulting in pregnancy.

PREPARATION

- PowerPoint slides on “Follow-Up”
- Computer and LCD
- Whiteboard and appropriate marker

TIME ALLOTMENT

30 minutes

### Teaching-Learning Process

| Introduction the session by providing an “Overview” for the topic. | State the “Learning Objectives” of the session as presented on PowerPoint slides. |
| Discuss the components of “routine follow-up” as presented on the slides. | Describe the types of follow-ups as presented on the slide. |

Follow-up

Learning Objectives

1. Routine Follow-Up
   • Scheduled at 7 days after surgery
2. Emergency Follow-Up
   • Not scheduled
   • Takes place at any time after surgery and discharge
1. Routine Follow-Up

- Perform the following:
  - Examine and clean operative site
  - Refer, appropriately, for management and treatment of possible complications not available at the facility
  - Remind the client to return to the clinic if she misses a period or has other symptoms of pregnancy
  - Accomplish client’s medical records

2. Emergency Follow-Up

- Assess client for possible:
  - Excessive bleeding at operative site
  - Internal bleeding
  - Bowel perforation
  - Bladder perforation
  - Failure of tubal occlusion resulting in pregnancy

- Check:
  - Vital signs
  - Wound dressing (dry or soaked?)
  - Abdomen

Within 3 days post-operative

2. Emergency Follow-Up

- Perform:
  - Obtain chronological information: problems during the procedure or recovery period, development of problems or increase in discomfort, and any medications taken or treatments obtained.
  - Review of the medical/surgical record
  - Examination of the client
  - Referral if facility is not capable of managing the complication

Discuss the components of “emergency follow-up” as presented on the slides.

---

Failure of Tubal Occlusion

**Pregnancy (intrauterine or ectopic)**

- Signs of ectopic pregnancy:
  - amenorrhea
  - lower abdominal pain
  - abnormal uterine bleeding
  - pallor (later sign when ruptured)

- Management
  - Explain to client the condition
  - Refer to OB-Gyn for further management

Tell participants that:

- Tubal occlusion (BTL) is one of the most effective methods of contraception.
- Failure is unlikely after minilaparotomy because the surgeon has an opportunity to examine the tube under direct vision.
- However, even if the risk is low, failure resulting to pregnancy is a possibility.
- And, with pregnancy, the possibility of

**NARRATIVE**

A follow-up visit should be scheduled at the time of surgery to take place within seven days of surgery and, when possible, should be conducted by the operating surgeon. However, it may be more practical for another member of the surgical team to examine the client, or for the client to visit her nearest health center. A trained, qualified health professional who is not a surgeon can conduct the examination and manage minor complications. If another health center provides follow-up care for minilaparotomy clients, its staff must be trained to do a careful examination and must communicate any observed complication to the facility where the surgery took place.

**ROUTINE FOLLOW-UP**

During the routine follow-up visit, staff assesses the client to determine if she has any side effects or complications related to the surgery. In addition to looking for medical problems, staff looks for signs that the client may be experiencing dissatisfaction, regret, or maladjustment related to the procedure.

Staff conducting routine follow-up must check the medical record or referral form to ascertain the background information of the client and of the surgical procedure. It is also important to determine if the client has experienced any problems or had any complaints since the surgery. Thus, staff should ask about the following:

- vaginal discharge or abnormal bleeding
- wound discharge or bleeding
- urinary difficulties
- fever, pain, or other distress

The following are performed during follow-up:

- operative site is examined to assess healing and the absence of infection. It is cleaned, and non-absorbable sutures, if used, are removed.
- refer to a physician or the surgeon for treatment of any complications identified during the examination
- making the appropriate referrals and follow-up appointments as needed.
- remind the client to return to the clinic if she misses a period or has other symptoms of pregnancy.
- medical complaints, diagnosis, and treatment at the follow-up visit are documented in the client’s medical records.

**EMERGENCY FOLLOW-UP**

An emergency follow-up visit may take place any time after the operation and client discharge. Clients requesting or making an emergency follow-up visit require immediate attention. Possible complications must be attended to before they can cause other problems or before they become life threatening. Staff interviewing clients who return to the clinic one to three days after surgery with a complaint must be
alert to the possibility of internal bleeding, bowel or bladder perforation, or infection.

In many cases, surgeons are not available during an emergency client visit. Often emergency clients first see a nurse. It is important for the surgeon to ensure that other staffs recognize the signs of possible complications and know how to manage them.

When conducting emergency follow-up, the clinic staff evaluates the client immediately and obtains chronological information from the client, including problems during the procedure or the recovery period, the development of problems or increase in discomfort, and any medications taken or treatments obtained. The medical record is reviewed if it is available.

If the examining staff is not a physician, the client refers her to a physician or the surgeon who decides whether treatment for the problem can be handled on an out-patient basis or whether the client must be hospitalized. They arrange an appropriate level of treatment for potentially serious complications. All problems and actions taken are noted on the client record form.

If a client requests emergency care at a health facility other than the site where she had surgery, a report of any complications and treatment should be sent to the facility where the procedure took place.

**FAILURE OF TUBAL OCCLUSION**

Tubal occlusion is one of the most effective methods of contraception, and failure is unlikely after minilaparotomy because the surgeon has an opportunity to examine the tube under direct vision, thus verifying that the procedure is being carried out appropriately. Nevertheless, even though the risk is low, staff must be aware that ectopic or intrauterine pregnancy is possible after any tubal occlusion procedure, and they must be prepared to identify such conditions early. Lower abdominal pain, amenorrhea, and abnormal uterine bleeding are prominent symptoms of an ectopic pregnancy. If staff suspects pregnancy, particularly ectopic, the client must be referred to the surgeon who explains the condition to the client and manages her condition appropriately (includes referral for diagnosis and/or further management).
Session 13

ACTION PLAN

OVERVIEW

Training courses are only as good as the learned training skills and knowledge applied by the trainees when they return to their original work areas. Developing and implementing an Action Plan is one of the ways to ensure that trained service providers transform learned training theory into reality in their workplaces. Application of a newly acquired skill requires the opportunity, resources and motivation to apply the learning on the actual job situation. It is important to remember that skills need to be practiced soon after training or these skills will be lost and will never be applied. All training courses require post-training follow-up for monitoring and evaluation during which the trained surgeons receive guidance and opportunities for coaching and mentoring from their trainers. It is also the opportunity to determine the extent to which the action plan has been and is being implemented and to provide the necessary assistance to help resolve issues that may be impeding the implementation of the action plan.

This session provides guidance in developing an Action Plan that will help trained BTL surgeons to successfully implement regular quality BTL services in their work areas.

LEARNING OBJECTIVES

At the end of the session, the participants will be able to:

1. Assess their facilities’ suitability for the provision of ML-LA services.
2. Identify activities that will make them capable of providing ML-LA services in their facilities.
3. Develop an action plan so that they will be able to provide ML-LA services in their facilities.

PREPARATION

- PowerPoint slides on “Action Plan”; Computer and LCD
- Manila paper, permanent markers, whiteboard markers,
- Checklist on BTL/MLLA Service Requirements (Self-Assessment)
- Copies of blank Action Plan Matrix for participants to fill up

METHODOLOGY

- Lecturette-discussion
- Brainstorming
- Individual Work
- Presentation in plenary
**TIME ALLOTMENT:** 2 hours

Self-Assessment

Instruct participants:
- To turn their handbooks to the “Checklist on BTL/MLLA Service Requirements” on p. 158. (Also found in Annex E p. 245 Facilitator’s Guide)
- Accomplish the self-assessment checklist.
- For items marked as (x) (unavailable) corresponding activities for having the requirement available should be determined and written on the Action Plan matrix.

Introduce the “Action Plan” matrix.
Tell participants that this is the matrix they will be using in developing their action plans.

Participants should refer to the Narrative portion of their handbooks for very important activities they should consider to include as part of their action plans.

Distribute the matrix to participants.
Instruct participants to fill up the matrix with their activities, expected outcomes, time frame, resources needed and costing, as needed, and responsible person(s) for completing the activity.

Remind participants that:
- The “responsible person(s)” should include themselves as this is an action plan for their implementation.
- The “time frame” should be the date the activity should have been completed.

Divide participants into groups corresponding to the number of facilitators. Facilitators in each of the groups guide participants as they develop their action plans.
Ask a number of participants at random to present their action plan.
NARRATIVE

Action planning is the process of intentionally and purposively writing down the next steps or activities that need to be done, when these steps need to be done, who will take responsibility for making sure that these steps are actually done, and enumerating the resources or inputs needed to actually do these next steps in order to realize certain strategic objectives.

Developing an action plan that indicates how and when new skills will be applied increases the likelihood of successful BTL services implementation. It likewise provides the opportunity for the trained BTL surgeon to establish how his/her newly acquired skills and knowledge will positively contribute to the improvement of his/her performance and the impact this will make on program goals and objectives.

ASSESSING SUITABILITY FOR THE PROVISION OF ML-LA SERVICES

In order to standardize requirements or expectations of a BTL-capable facility, a checklist of minimum requirements for BTL-MLLA service provision has been developed. This guide is categorized into minimum requirements for the facility, for its staffing, for its infection prevention practices, and for recording/reporting.

Please refer to Annex D on page 158 of Participant’s Handbook: Checklist on ML-LA Service Requirements (Self-Assessment) (Also found in Annex E p. 245 Facilitator’s Guide)

IDENTIFYING ACTIVITIES TO ENSURE SUCCESSFUL PROVISION OF ML-LA SERVICES

In ensuring the success of a BTL program in a hospital and consequently in the community, the trained BTL surgeon must be taken into consideration a number of important information and key factors. The following describes some of these programmatic elements that the trained surgeon must be well-informed of and which must be considered in developing and, later, implementing the action plan.

1. BTL client demand generation – all over the country, there is a huge estimated number of couples who no longer desire to have any more children and yet do not have access to permanent methods such as BTL. It is important therefore to make efforts at disseminating information about the availability of BTL services in the trained BTL surgeons’ hospitals upon their return from training:
   a. Generating BTL clients from outside the hospital
      i. Link with public and private partners of the FP-MNCHN Service Delivery Network (SDN) of service providers and facilities in the area informing them of the regular schedule of BTL services in the hospital and the other related information – coordinate with RHUs, CHTs, 4Ps/CCTs/KP implementers
      ii. Coordinate with potential sources of clients such as formal employment sectors (workplaces – big companies) or groups of companies such as chambers, federations; informal workforce groups (cooperatives, peoples’ organizations, civic organizations, etc.); academic institutions; NGOs, etc.
b. Generating clients from within the hospital
   i. FP education and information dissemination activities through health classes or posters, etc. must be regular features in hospitals, especially in OB wards, out-patient clinics or in waiting areas. Clients participating in these classes must be linked to FP and BTL services offered within the hospital. This includes FP counseling by trained hospital staff who can then refer interested clients for BTL.
   ii. Inform all hospital staff of schedule of regular BTL services and other related information
   iii. Posters with BTL services information may be placed in all hospital bulletin boards, wards, out-patient clinics, and other conspicuous areas
   iv. An intra-hospital referral system must be put in place for a smooth flow for all potential BTL clients – patients, watchers, hospital staff/employees – to access FP counseling and eventually the actual BTL procedures.

2. Financing for BTL services (possible sources of funding support)
   a. PhilHealth benefits
      i. PhilHealth pays case payment rates of P 4,000.00 for each case of BTL performed by a PhilHealth-accredited BTL surgeon in a PhilHealth-accredited primary or secondary or tertiary care hospital on an eligible PhilHealth member (PhilHealth Circular no. 16, series 2008; implementation of the PhilHealth benefit package for VSC including BTL/MLLA and NSV)
      ii. 4Ps patients receiving CCT are likewise PhilHealth indigent cards holders and are automatically entitled to this benefit (PhilHealth Circular No. 011-2011: New PhilHealth Case Rates for Selected Medical Cases and Surgical Procedures and the No Balance Billing Policy)
      iii. NBB is required for public hospitals BUT is optional for private hospitals
   b. The hospital department of surgery or OB-GYNE must regularly request hospital management that some allocations for the usual drugs, supplies, etc. needed for regular BTL services be included in the hospital budget and procurement plan.
   c. Co-financing schemes may be explored with SDN partners, workplaces (using Corporate Social Responsibility funds), LGUs (from MNCHN grant or IRA), etc.

3. The availability of needed drugs, expendable supplies, instruments and equipment for performing BTL-MLLA must be regularly monitored and therefore ensured by hospital staff with supervision from the trained BTL surgeon/s, in coordination with hospital management.

4. Likewise, proper recording and reporting forms and systems must be established as part of good quality BTL services in the hospital:
   a. FP Form I – must be available and always used for ALL potential FP clients whether or not they choose a particular FP method. This is filled up by the field health unit staff midwife or nurse trained in (FP-CBT level I) FP counseling and signed by the FP client if he/she chose a particular method. The filled up form is secured in a filing cabinet that cannot be easily accessed in order to maintain record confidentiality.
b. Informed Consent Form – this is different from the regular consent for admission and surgical procedure normally signed by patients upon admission to any hospital. This form contains six elements and is specific for clients choosing permanent FP methods of either BTL (for females) or No-Scalpel Vasectomy (for males). This form must be available at the OPD clinics where counseling occurs and at the operating room so that the trained BTL surgeon can verify the clients’ understanding and informed and voluntary decision-making/choice. It is the BTL surgeon who has ultimate responsibility for ensuring the BTL clients understand and sign this informed consent form.

c. Surgical and Anesthesia Record – the usual Operating Room surgical record may be used for the purpose of recording the BTL-MLLA surgical technique and anesthesia procedure. The trained BTL surgeon must make sure that he/she signs this record. This record will eventually be the basis for PhilHealth professional fee payment for the surgeon.

d. Properly filled up Informed Consent Forms (b) and Surgical/Anesthesia Records (c) will eventually be filed with the hospital’s records section. Information however will be summarized in the Operating Room logbook that is usually maintained in the Operating Room Complex of most hospitals.

e. Preferably, there should be a hospital staff trained in Field Health Services Information System (FHSIS) in order to capture the hospital’s FP accomplishments. These, BTL accomplishments, must be summarized using the M1 form of FHSIS and submitted to whichever reporting unit has jurisdiction over the hospital or depending on previously agreed reporting arrangements.

f. It will be helpful for clients who have undergone BTL to receive post-operative written instructions that they can bring home as reminders and which will be explained clearly to them prior to discharge from the hospital.

5. Trained BTL surgeons are likewise enjoined to provide their BTL services in areas where there are no trained BTL surgeons and no regular BTL services. This is called BTL Itinerant or Mobile service and is usually organized by the DOH-CHD or the LGU or as an initiative of the hospital itself as a response to the unmet demand for BTL in many areas across the nation. DOH-AO No. 153 series 2002 mandates DOH-retained regional hospitals and medical centers to coordinate with the DOH-CHD and the LGUs to provide these services.

a. Needless to say, all the above factors must be considered and put in place in order to ensure success of the itinerant BTL service.

b. It is advisable that an assessment visit to the host facility or the off-site hospital (the hospital where the itinerant services will be provided) be conducted by the trained BTL surgeon/s to assess the needed items and adjustments that should be made prior to the actual itinerant BTL service provision.

c. Additionally, proper screening of potential clients for BTL-MLLA must be coordinated with the host facility – these potential clients must be screened by the field health unit physicians or by physicians-staff of the host facility PRIOR to the arrival of the itinerant team. This is to ensure that only clients who are eligible for MLLA technique will come on the BTL day. This will minimize frustrations for both clients and surgeons. Women for whom MLLA cannot be done must be referred to the facility where spinal or general anesthesia can be employed instead of local anesthesia.
d. Arrangements and prior agreements on the process of PhilHealth claims (or other financing schemes, as applicable) as well as the distribution of professional fees, as applicable, must likewise be finalized before the actual conduct of the itinerant services.

e. As in hospitals with regular BTL services, accomplishments in host facilities where BTL itinerant services were performed should be recorded using the appropriate operating room reporting forms and summarized for submission using the FHSIS forms. These accomplishments should be submitted to whichever reporting unit has jurisdiction over the hospital (host facility) or depending on previously agreed reporting arrangements.

DEVELOPING AN ACTION PLAN

For this training course, action planning is intended to ensure the successful implementation of the BTL-MLLA program in the trained BTL surgeons’ workplaces upon their return from the training. It is therefore the process of making plans to operationalize the implementation of regular BTL services in the trained BTL surgeons’ hospitals.

Most action plans consist of the following elements:

- a statement of what must be achieved (the outputs or result areas);
- an enumeration of the steps or activities that have to be done to achieve what needs to be achieved;
- some kind of a time schedule for when each activity must take place and how long it is likely to take (when);
- a clarification of who will be responsible for making sure that each step is successfully completed (who);
- a clarification of the inputs/resources that are needed to implement the activity.

Below is a suggested template matrix:

ANNEX A.
Instruments and Supplies for BTL/MLLA

Instruments used for inserting the uterine elevator

- Gauze
- Metal cup with antiseptic (Betadine)
- Sponge forceps
- Graves speculum
- Ramathibodi uterine elevator
Instrument tray used for performing minilaparotomy

- 1 set of Apelo retractors
- 4 straight Kelly forceps, 8 inches
- Tissue forceps
- Needle holder
- Hypodermic syringe (10 or 20 cc.) with needle
- Blade holder with blade
- Metzenbaum scissors
- Gauze
- Chromic 2-0 atraumatic suture
ANNEX B.

Medical eligibility criteria for contraceptive use

Fourth edition, 2009

A WHO FAMILY PLANNING CORNERSTONE

World Health Organization
SURGICAL STERILIZATION PROCEDURES (STER)

Given that sterilization is a surgical procedure that is intended to be permanent, special care must be taken to assure that every client makes a voluntary informed choice of the method. Particular attention must be given in the case of young people, nulliparous women, men who have not yet been fathers, and clients with mental health problems, including depressive conditions. All clients should be carefully counselled about the intended permanence of sterilization and the availability of alternative, long-term, highly effective methods. This is of extra concern for young people. The national laws and existing norms for the delivery of sterilization procedures must be considered in the decision process.

Transcervical methods of female sterilization are not addressed in these recommendations.

There is no medical condition that would absolutely restrict a person’s eligibility for sterilization, although some conditions and circumstances will require that certain precautions are taken, including those where the recommendation is C (caution), D (delay), or S (special). For some of these conditions and circumstances, the theoretical or proven risks may outweigh the advantages of undergoing sterilization, particularly female sterilization. Where the risks of sterilization outweigh the benefits, long-term, highly effective contraceptive methods are a preferable alternative. Decision in this regard will have to be made on an individual basis, considering the risks and benefits of sterilization versus the risks of pregnancy, and the availability and acceptability of highly effective, alternative methods.

The following classification of conditions into the four different categories is based on an in-depth review of the epidemiological and clinical evidence relevant to medical eligibility. Sterilization procedures should only be performed by well-trained providers in appropriate clinical settings using proper equipment and supplies. Appropriate service delivery guidelines, including infection-prevention protocols, should be followed to maximize client safety.

DEFINITIONS

A  Accept  There is no medical reason to deny sterilization to a person with this condition.

C  Caution  The procedure is normally conducted in a routine setting, but with extra preparation and precautions.

D  Delay  The procedure is delayed until the condition is evaluated and/or corrected. Alternative temporary methods of contraception should be provided.

S  Special  The procedure should be undertaken in a setting with an experienced surgeon and staff, equipment needed to provide general anaesthesia, and other back-up medical support. For these conditions, the capacity to decide on the most appropriate procedure and anaesthesia regimen is also needed. Alternative temporary methods of contraception should be provided, if referral is required or there is otherwise any delay.
### FEMALE SURGICAL STERILIZATION

Sterilization does not protect against STI/HIV. If there is risk of STI/HIV (including during pregnancy or postpartum), the correct and consistent use of condoms is recommended, either alone or with another contraceptive method. Male latex condoms are proven to protect against STI/HIV.

Pre/Post-Test Questionnaire for Skills Training on MLLA

CODE ________

SKILLS TRAINING ON MINILAP UNDER LOCAL ANESTHESIA
Pre/Post-Test

NAME: ____________________________ Date: ______________

Instructions: Write T on the space provided for if the answer is TRUE and F if FALSE.

COUNSELING

_____ 1. An objective of family planning counseling is to provide information necessary to make a reasoned, voluntary decision about their fertility.

_____ 2. Counseling is more costly for programs as service providers have to take time to provide it to clients.

_____ 3. Because BTL is intended to end the woman’s ability to have children, spousal consent is required.

_____ 4. Though there are available services for reversal, clients must consider BTL as a permanent method for ending fertility.

_____ 5. Risks and side effects of BTL should not be mentioned during counseling as these make clients change their decisions to undergo the procedure.

_____ 6. A good opportunity to counsel women on family planning is during labor.

INFECTION PREVENTION

_____ 7. Instruments used during the surgery should be immediately cleaned with soap and water after the procedure.

_____ 8. Changing the needle and using the same syringe in high volume settings is safe and cost effective.

_____ 9. Controlling the number and activity of people in the operating room minimizes the level of microbial contamination.

_____ 10. The operating room should be thoroughly cleaned at least once a month.

PREPARATION FOR SURGERY

_____ 11. There are medical conditions that would absolutely restrict a woman’s eligibility for BTL.

_____ 12. Screening of a potential minilaparotomy client should include at least a complete medical history, general physical examination, and pelvic examination.

_____ 13. BTL by minilap may be performed at any time during the menstrual cycle.
14. A woman with history of gestational diabetes can tolerate minilap under local anesthesia.
15. Hemoglobin/hematocrit determination should be part of a routine laboratory examination for potential clients for minilap under local anesthesia.
16. A woman who has undiagnosed vaginal bleeding should not have a minilap until the cause of bleeding is determined.
17. A contraindication for performing a minilap under local anesthesia is a retroverted uterus.
18. It is sufficient that clients for minilap under local anesthesia receive verbal instructions on the preparation for the procedure.
19. Prior to performing a sterilization procedure, the surgeon must talk with the client to ensure that she understands the procedure she has requested.

MINILAP UNDER LOCAL ANESTHESIA

20. Studies have shown that local anesthesia for BTL by minilap is associated with lesser risk for unexpected and life-threatening complications and more cost-effective as compared to regional and general anesthesia.
21. Successful use of local anesthesia for a minilap procedure involves infiltration of at least 15 cc of lidocaine 2%.
22. When infiltrating lidocaine to produce local anesthesia, the surgeon must be sure that only the skin and subcutaneous tissue are infiltrated.
23. Sharp dissection of the subcutaneous tissues is avoided as this increases the risk for more bleeding.
24. In closing the abdominal incision, it is necessary to close the peritoneum.
25. It is the surgical assistant’s role to access and identify the tubes.

POST-OPERATIVE MANAGEMENT

26. After a minilap, the client should return to the clinic within a week of the surgery.
27. It is necessary to prescribe antibiotics to clients after minilap.
28. Post-operative assessment should, at least, include observation and recording of the client’s vital signs, checking her general condition and comfort, and checking for bleeding from the operative site.
29. The client is usually discharged within 1 hour after the procedure.
30. Tubal occlusion is a 100% effective method of contraception so that pregnancy after the procedure should not be considered.
ANNEX D.
Pre/Post-Test Questionnaire for Skills Training on MLLA

ANSWER KEY

COUNSELING

T 1. An objective of family planning counseling is to provide information necessary to make a reasoned, voluntary decision about their fertility.

F 2. Counseling is more costly for programs as service providers have to take time to provide it to clients.

F 3. Because BTL is intended to end the woman’s ability to have children, spousal consent is required.

T 4. Though there are available services for reversal, clients must consider BTL as a permanent method for ending fertility.

F 5. Risks and side effects of BTL should not be mentioned during counseling as these make clients change their decisions to undergo the procedure.

F 6. A good opportunity to counsel women on family planning is during labor.

INFECTION PREVENTION

F 7. Instruments used during the surgery should be immediately cleaned with soap and water after the procedure.

F 8. Changing the needle and using the same syringe in high volume settings is safe and cost effective.

T 9. Controlling the number and activity of people in the operating room minimizes the level of microbial contamination.

F 10. The operating room should be thoroughly cleaned at least once a month.

PREPARATION FOR SURGERY

F 11. There are medical conditions that would absolutely restrict a woman’s eligibility for BTL.

T 12. Screening of a potential minilaparotomy client should include at least a complete medical history, general physical examination, and pelvic examination.

T 13. BTL by minilap may be performed at any time during the menstrual cycle.

T 14. A woman with history of gestational diabetes can tolerate minilap under local anesthesia.

F 15. Hemoglobin/hematocrit determination should be part of a routine laboratory examination for potential clients for minilap under local anesthesia.

T 16. A woman who has undiagnosed vaginal bleeding should not have a minilap until the cause of bleeding is determined.

F 17. A contraindication for performing a minilap under local anesthesia is a retroverted uterus.
18. It is sufficient that clients for minilap under local anesthesia receive verbal instructions on the preparation for the procedure.

19. Prior to performing a sterilization procedure, the surgeon must talk with the client to ensure that she understands the procedure she has requested.

**MINILAP UNDER LOCAL ANESTHESIA**

20. Studies have shown that local anesthesia for BTL by minilap is associated with lesser risk for unexpected and life-threatening complications and more cost-effective as compared to regional and general anesthesia.

21. Successful use of local anesthesia for a minilap procedure involves infiltration of at least 15 cc. of lidocaine 2%.

22. When infiltrating lidocaine to produce local anesthesia, the surgeon must be sure that only the skin and subcutaneous tissue are infiltrated.

23. Sharp dissection of the subcutaneous tissues is avoided as this increases the risk for more bleeding.

24. In closing the abdominal incision, it is necessary to close the peritoneum.

25. It is the surgical assistant’s role to access and identify the tubes.

**POST-OPERATIVE MANAGEMENT**

26. After a minilap, the client should return to the clinic within a week of the surgery.

27. It is necessary to prescribe antibiotics to clients after minilap.

28. Post-operative assessment should, at least, include observation and recording of the client’s vital signs, checking her general condition and comfort, and checking for bleeding from the operative site.

29. The client is usually discharged within one hour after the procedure.

30. Tubal occlusion is a 100% effective method of contraception so that pregnancy after the procedure should not be considered.
ANNEX E.
Checklist on MLLA Service Requirements (Self-Assessment)

**Instruction:** Place a (√) in the adjacent box if the requirement is presently available in your facility and an (X) if it is **not**.

### A. FACILITY

The facility is adequately equipped and supplied as it has the following:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>Signage that informs clients of services, including FP, provided at the clinic and clinic hours.</td>
</tr>
<tr>
<td>2.</td>
<td>Clean and well ventilated client areas free from garbage, pests and insects.</td>
</tr>
<tr>
<td>3.</td>
<td>Waiting area with seats for clients.</td>
</tr>
<tr>
<td>4.</td>
<td>All-methods poster displayed in an area where clients can see.</td>
</tr>
<tr>
<td>5.</td>
<td>IEC materials available and are being used.</td>
</tr>
<tr>
<td>6.</td>
<td>An area for consultation and counseling that:</td>
</tr>
<tr>
<td></td>
<td>• has a table and chairs.</td>
</tr>
<tr>
<td></td>
<td>• provides auditory and visual privacy.</td>
</tr>
<tr>
<td></td>
<td>• has an examination table with Kelly pad.</td>
</tr>
<tr>
<td></td>
<td>• has sink with running water, liquid or bar soap, and clean, dry towel for washing and drying hands.</td>
</tr>
<tr>
<td></td>
<td>• has locked storage for medicines and supplies.</td>
</tr>
<tr>
<td></td>
<td>• has locked filing cabinet to keep clients’ records.</td>
</tr>
<tr>
<td>7.</td>
<td>Temporary methods available as possible alternatives to sterilization.</td>
</tr>
<tr>
<td>8.</td>
<td>Has enough instruments for MLLA:</td>
</tr>
<tr>
<td></td>
<td>• Ramathobodi uterine elevator</td>
</tr>
<tr>
<td></td>
<td>• Gauze</td>
</tr>
<tr>
<td></td>
<td>• Metal cup with antiseptic (Betadine)</td>
</tr>
<tr>
<td></td>
<td>• Sponge forceps</td>
</tr>
<tr>
<td></td>
<td>• Graves speculum</td>
</tr>
<tr>
<td></td>
<td>• Straight Kelly forceps, 8 inches</td>
</tr>
<tr>
<td></td>
<td>• Sets of Apelo retractors</td>
</tr>
<tr>
<td></td>
<td>• Tissue forceps</td>
</tr>
<tr>
<td></td>
<td>• Needle holder</td>
</tr>
<tr>
<td></td>
<td>• Hypodermic syringe (10 or 20 cc.) with needle</td>
</tr>
<tr>
<td></td>
<td>• Blade holder with blade</td>
</tr>
<tr>
<td></td>
<td>• Metzenbaum scissors</td>
</tr>
</tbody>
</table>
9. Has materials, supplies and drugs for IV infusion, sedation, and analgesia.

10. Basic emergency equipment and instruments available and functional.
   - Battery-operated back-up light source
   - Stethoscope
   - Sphygmomanometer
   - Oral airways
   - Nasal airways
   - Suction machine with tubing
   - Ambubag
   - Anesthesia face mask and tubing and oxygen nipple
   - Oxygen tank with reducing valve and flowmeter
   - Blanket
   - Emesis basin
   - Syringes and needles
   - Intravenous infusion sets and fluids
   - Adhesive strapping
   - Sterile laparotomy instruments
   - Laryngoscope
   - Endotracheal tubes

11. Basic emergency drugs available.
   - Adrenalin
   - Atropine sulphate
   - Naloxone
   - Corticosteroids
   - Physostigmine or Flumazenil
   - Aminophylline
   - Antihistamine
   - Diazepam

12. Has provisions for infection prevention such as:
   - functional autoclave
• gloves (i.e., utility, examination, and sterile)
• antiseptics (i.e., isopropyl 70% alcohol, betadine)
• bleach for preparing 0.5% decontaminating solution
• detergent
• plastic containers for soaking and cleaning used instruments.
• covered waste baskets lined with appropriate color coded plastic bags in client areas (i.e., waiting area, consultation room)
• work area for cleaning instruments, Kelly pad, and mop.
• area for storing sterile instruments and supplies
• access to potable water.
• color-coded garbage containers for different types of wastes
  ✓ Black plastic lining for general, dry, non-infectious waste
  ✓ Green plastic lining for general, wet, non-infectious waste
  ✓ Yellow for infectious/pathological waste
• container for sharps.
• mops and rags

13. Has an area for interim storage of waste that is minimally accessible to staff, clients, and visitors.

B. STAFFING

1. Available trained FP counselor(s) providing regular FP counseling activities.
2. Staff for safe provision of MLLA services:
   • Trained surgeon
   • Surgical assistant
   • Circulating nurse
   • Client monitor
3. Support staff skillful in managing emergencies available.
4. Staff skillful in CPR available.
5. Competent staff for MLLA follow-up visit available.

C. INFECTION PREVENTION PRACTICE

1. Cleanliness observed at OR and clinic.
2. Restricted areas and OR policies observed.
3. Decontamination with Chlorine solution is practiced.
4. Adequate processing of instruments practiced.
5. Appropriate asepsis and antisepsis procedures practiced for clients and surgical team.

6. Proper storage of sterile instruments, gowns, linens.

7. Appropriate waste disposal practices implemented (e.g., use of separate sharps containers and clinic wastes)

### D. FORMS, RECORDS and REPORTS

1) The following forms available:
   - FP Form 1
   - Informed Consent Form
   - Operative Record
   - Post-operative instructions form

2) Good system of keeping clients’ records on file.

3) System for submission of FP caseload to the PHO established.
ANNEX F.
Course Evaluation
(To be completed by trainees)

Course Title: ___________________________ Date: __________________

A. Training Aspects (Course Content and Training Methods)

Instructions: Please circle the number that reflects your reaction to the session presentation using the following rating scale:

5 - Excellent  4 - Good  3 - Average  2 - Below Average  1 - Poor

Achievement of course objectives  5  4  3  2  1
Achievement of personal objectives  5  4  3  2  1
Relevance of the course to your job  5  4  3  2  1
Organization of the course  5  4  3  2  1
Usefulness of the training materials  5  4  3  2  1
Opportunity to participate in training activities  5  4  3  2  1
Opportunity to ask questions and interact with trainers  5  4  3  2  1

Course length: Too long ______ Too short ______ Just right ______

What topics in this course do you think will be most useful to you in your work?

On which topics would you have liked more information or preferred to spend more time?

On which topics would you have liked less information or preferred to spend less time?
B. **Administrative Aspects (Logistics):**

**Instructions:** Please circle the number that reflects your reaction to the session presentation using the following rating scale:

</table>
### SUBUMBILICAL MINILAPAROTOMY

20. Dissects the subcutaneous layer bluntly with Kelly forceps or retractors until the anterior rectus fascia is visualized and exposed. Maintains midline dissection.

21. Instructs assistant appropriately to expose the operative field.

22. Incises the fascia creating a transverse slit through the whole thickness of the fascia.

23. Grasps the edges of the slit with Kelly or Allis forceps.

24. Lifts the fascia while extending the incision transversely.

25. Elevates the peritoneum by grasping it at 2 points 1-2 cm apart with hemostats.

26. Checks that the bowels, omentum, or bladder have not been grasped inadvertently with the peritoneum by checking translucency and thinness.

27. Opens the peritoneum and repositions the retractors inside the abdominal cavity.

### DELIVERY AND OCCLUSION OF THE FALLOPIAN TUBES

28. Pushes the uterus toward the opposite side of the tube being accessed.

29. Gently moves the incision to the tube that is being accessed with the assistant following the direction of the surgeon using the other retractor.

30. Clears out the omentum or bowels covering the fundus.

31. Grasps the tube with Kelly forceps.

32. Pulls the tube further and “walks through” it until the fimbrial end is identified. Does not lock the forceps as this is done.

33. Creates a 1-2 cm. loop of tube.

34. Ties the loop of tube tightly and with a surgical knot while the assistant holds the Kelly with the tube.

35. Holds the sutures with forceps.

36. Excises the tube above the knot leaving at least 0.5 cm. tubal stump.

37. Examines the tubal stump for bleeding.

38. Cuts the suture above the knot so that the tube returns to the abdomen.

ANNEX H.
Guidelines on Post-Training Follow-Up and Monitoring of Trainees of the “Skills Training on Minilaparotomy under Local Anesthesia”

Preparatory Activities

1. One month prior to visit

Ensure communication (i.e., letter followed by phone call, if possible) with the head of the trainee’s facility, the trainee’s supervisor and the trainee to inform them of:

- Purpose of the visit which may be but not be limited to:
  - Determine if the trainee-service provider is able to competently provide BTL/MLLA services as taught during the “Skills Training on Minilaparotomy under Local Anesthesia” course.
  - Determine if the site is capable of supporting the trainee in the provision of quality BTL/MLLA services as he/she has been trained.
  - Identify problems the trainee may have in applying the knowledge and skills learned.
  - Provide trainee with technical assistance, as necessary.
  - Assist the trainee in finding solutions to these problems.
  - Determine if training has resulted in client satisfaction with the services provided in the trainee’s facility.

- Date of the visit

- What the trainee needs to prepare: charts of clients provided with BTL/MLLA services, availability of client(s) during the visit.

2. Two weeks prior to visit

- Obtain confirmation of the scheduled visit

- Prepare materials you will need, such as:
  - Performance monitoring checklist (2 copies/trainee: a copy to be left with trainee and another for the monitoring agency) – see page 261: Annex I. Post-Training Monitoring and Follow-Up Checklist of Skills Training on Minilaparotomy under Local Anesthesia Graduates
  - Copy of the letter previously sent informing the trainee of your visit
  - Copy of the action plan (developed during the training course)

3. Immediately prior to the visit

- Prepare for travel arrangements

4. Plan to be on time for the site visit
During the Follow-up

1. Conduct a courtesy call on the head of the facility.
   - Explain the purposes of the follow-up visit which are to:
     - Determine if the trainee-service provider is able to competently provide BTL/MLLA services as taught during the “Training on BTL by MLLA” course.
     - Determine if the site is capable of supporting the trainee in the provision of quality BTL/MLLA services as he/she has been trained.
     - Identify problems the trainee may have in applying the knowledge and skills learned.
     - Provide trainee with technical assistance, as necessary.
     - Assist the trainee in finding solutions to these problems.
     - Determine if training has resulted in client satisfaction with the services provided in the trainee’s facility.

2. Arrange to interview the trainee’s immediate supervisor.
   - The following are some informal interview questions the trainer can ask the supervisor:
     - How did training improve the trainee’s BTL/MLLA performance? (increased number of BTL cases since training? Regular BTL service now available?)
     - Is the facility now receiving referrals from Service Delivery Network partners and performing BTL on these referrals? Explain how the referral works.
     - Has there been a change in the infection prevention practices in the clinic and as practiced by the trainee? In what way?
     - Has the trainee been involved in activities to improve the quality of FP services in the facility (e.g., work planning activities, forecasting and allocation of commodity needs, accomplishment of reports, resource mobilization)?

3. Interview the trainee and observe his/her performance
   - Review the action plan developed during the course. Determine the extent to which the trainee has implemented the action plan.
     - Find out whether he/she is able to apply the concepts and provide BTL/MLLA services as learned in the course.
     - Validate performance with a review of clients’ charts and other pertinent records (e.g., referral slips)
     - If trainee expresses not being able to apply fully the concepts and skills learned in the course, ask for the constraints he/she is encountering. Include these as part of the “Issues” that need to be addressed.
- **COACH** the trainee to reinforce the critical skills learned during training by:
  
  o Reviewing with her the BTL/MLLA performance monitoring checklist as the basis of the evaluation. Ask the trainee if there are any tasks in the checklist s/he finds difficult to perform.
  
  o Observing **actual BTL-MLLA** performance/s in the trainee’s workplace/hospital during the follow up monitoring visit, noting observations using the checklist and providing supportive feedback or corrections as needed.
  
  o Checking and assisting him/her, as needed, on the performance of the steps in the provision of MLLA.
  
  o Providing feedback by commending him/her on tasks that were performed well followed by recommendations for improvement.
  
  o Asking what additional assistance s/he may need to improve his/her performance.
  
  o Arrange for schedule of return visit if trainee has not performed satisfactorily and to check if recommendations are implemented.
  
  - Provide trainee with the feedback of his/her supervisor.
  
  - Process the observations by listing items rated as “2” in the “Good Points” portion. Those rated as “1” and “0” under the “Issues” heading. For each of the issues, discuss recommendations for improvement and the agreed time frame for completion of the recommended activities.
  
  - Thank the trainee for his/her cooperation.

4. As time allows, post-BTL clients may be interviewed using the Client Interview Form (on page 273 Annex J.)

5. Conduct an exit conference with the supervisor/head of facility.
   
   • Present a summary of the results of the trainee observation and assistance they can provide in improving the trainee’s performance.

**After the follow-up visit**

• Prepare the report.

• Send copies of the report to appropriate agencies.

### A. FACILITY

The facility is adequately equipped and supplied as it has the following:

1. Signage that informs clients of services, including FP, provided at the clinic and clinic hours.

2. Clean and well ventilated client areas free from garbage, pests and insects.

3. Waiting area with seats for clients.

4. All-methods poster displayed in an area where clients can see.

5. IEC materials available and are being used.

6. An area for consultation and counseling that:
   - has a table and chairs.
   - provides auditory and visual privacy.
   - has an examination table with Kelly pad.
   - has sink with running water, liquid or bar soap, and clean, dry towel for washing and drying hands.
   - has locked storage for medicines and supplies.
   - has locked filing cabinet to keep clients’ records.

7. Clean toilet with running water accessible to clients and staff.

8. Dressing room for clients and OR staff.

9. Operating room that is spacious and restricted with

### Bilateral Tubal Ligation by Minilaparotomy under Local Anesthesia

#### E. PERFORMANCE OF BTL/MLLA  
(by observation)

**SUPRAPUBIC BTL/MLLA**

**PREPARING FOR SURGERY**

1. Ensures that client has emptied her bladder before entering the operating room.
2. Ensures that needed instruments are available and properly processed.
3. Ensures that needed medications/drugs for the procedure and for possible emergency are available.
4. Ensures that intravenous line is properly inserted by the circulating nurse.
5. Positions client in dorsal lithotomy position.
6. Washes hands with soap and water.
7. Puts on HLD or sterile gloves.
8. Swabs the perineal area with povidone solution assisted by the circulating nurse.
10. Inserts the vaginal speculum.
11. Checks for abnormalities of the cervix (e.g., erosions, mass, discharge).
12. Swabs the cervix with povidone.
13. Gently inserts the uterine elevator into the uterus without touching the vaginal walls.
14. Checks that the uterine elevator is in place by depressing it and noting the bulge created on the abdomen by the uterine fundus.
15. Repositions client into dorsal supine position.
16. Instructs circulating nurse to administer Meperidine 50 mg. by slow IV and Diazepam 5 mg. initially and add 5 mg. if client is observed to be anxious.

**INFLTRATION OF LOCAL ANESTHESIA**

17. Chooses the incision site as just below the umbilicus.

18. Infiltrates the abdominal wall (using the fan-shaped technique) with 10 cc. 2%lidocaine or 20 cc. 1%lidocaine.

19. Checks for effective anesthesia block by pinching with tissue forceps the subumbilical area.

**ENTERING THE ABDOMEN**

20. Pulls the skin taut to make a transverse incision approximately 2-3 cm. in length beneath the umbilicus.

21. Dissects the subcutaneous layer bluntly with Kelly forceps or retractors until the anterior rectus fascia is visualized and exposed. Maintains midline dissection.

22. Incises the fascia creating a vertical slit through the whole thickness of the fascia.

23. Grasps the edges of the slit with Kelly or Allis forceps.

24. Lifts the fascia while extending the incision vertically.

25. Elevates the peritoneum by grasping it at 2 points 1-2 cm apart with hemostats.

26. Checks that the bowels, omentum, or bladder have not been grasped inadvertently with the peritoneum.

**F. EMERGENCY PREPAREDNESS (by inspection and interviews)**

1. Basic emergency equipment and instruments available and functional.
   - Battery-operated back-up light source
   - Stethoscope
   - Sphygmomanometer
   - Oral airways
   - Nasal airways
   - Suction machine with tubing
   - Ambubag
   - Anesthesia face mask and tubing and oxygen nipple
   - Oxygen tank with reducing valve and flowmeter
   - Blanket
   - Emesis basin
   - Syringes and needles
   - Intravenous infusion sets and fluids
   - Adhesive strapping
   - Sterile laparotomy instruments
   - Laryngoscope
   - Endotracheal tubes

2. Basic emergency drugs available.

3. Staff for safe provision of BTL/MLLA services:
   • Trained surgeon
   • Surgical assistant
   • Circulating nurse
   • Client monitor

4. Support staff skillful in managing emergencies available.

5. Staff skillful in CPR available.

G. RECOVERY and FOLLOW-UP of CLIENTS

1. Recovery area available, well lighted and ventilated.

2. Written post-op instructions for client given on discharge.

3. Policy for first follow-up visit maintained.

4. Competent staff for the follow-up visit available.

H. REVIEW of RECORDS and REPORTS (review trainee’s records of BTL/MLLA clients)

1. Client records are complete, properly filled up and signed by providers.

2. Signed informed consent attached.

4. Reports on caseload submitted to the PHO.
**Good Points** *(choose among tasks rated as “2”).* Use back for more space.

ANNEX J.
Client Interview Form

Name of Service Provider ___________________ Course Dates ____________________
Address _______________________________________________________________________

Directions: Introduce yourself to the client. Explain that the purpose of the interview is to learn how clients feel about services offered at the facility and to get the client’s suggestions on how services might be improved. Stress that the interview is confidential and that the client’s name will not be used. Adapt the questions listed here to your facility and the client you are interviewing. Record any additional information the client volunteers to give. Thank the client for her/his assistance.

1. Why did you come to the clinic today?
2. Did you get what you came for? If not, why not?
3. Have you been given information about family planning? _____ Yes _____ No
   If yes, what methods did you hear about?
   If no, would you have liked to get family planning information? _____ Yes _____ No
4. If you came for family planning, did you get the method you wanted? _____ Yes _____ No
   If yes: What instructions were you given about your method?
   Do you have any more questions about your method?
   If no: Why not?
5. What do you like best about this clinic?
6. What do you like least about this clinic?
7. What suggestions do you have to help us improve services at this clinic?
8. Is there anything else you would like to tell us?
