7. REFERENCE ORGANIZATION NAME AND ADDRESS Food and Feed Grain Institute Kansas State University, Manhattan, Kansas 66506		
8. SUPPLEMENTARY NOTES (Sponsoring Organization, Publisher, Availability) (In Food & Feed Grain Institute. Special rpt. no. 3)		
9. ABSTRACT The main purpose of the study was to assemble information on the capacity, location, and types of grain storage currently available in developing countries, and to assess the storage conditions, problems, and deterrents to improvement. Data on storage capacities and locations for many developing countries are not readily available. A more complete study should be undertaken by a multilateral international organization. Data are included here for these Latin American countries; Argentina, Bolivia, Chile, Colombia, Dominican Republic, Ecuador, El Salvador, Guatemala, Guyana, Haiti, Honduras, Mexico, Panama, Peru, Trinidad, Uruguay, and Venezuela. For these African countries: Botswana, Chad, Dahomey, Ethiopia, Gambia, Ghana, Ivory Coast, Kenya, Lesotho, Liberia, Mali, Niger, Nigeria, Senegal, Sierra Leone, Somalia, Rep. of S. Africa, Swaziland, Tanzania, Togo, Upper Volta, Aire, Zambia, Entente States. For Asian countries: Indonesia, Korea, Malaysia/Singapore, Philippines, Taiwan, South Vietnam. For the Near East: Afghanistan, Algeria, Bangladesh, Egypt, India, Iran, Jordan, Lebanon, Morocco, Nepal, Pakistan, Syria, Tunisia, Turkey. Much of the deterioration and loss of grain occurs not as a result of poor facilities but rather poor management of the grain in storage. Local managers lack knowledge of basic principles of grain storage.

PREFACE

This report was undertaken as a first attempt at gathering data available on grain storage capacities and locations in developing countries throughout the world.

The project, Contract AID-otr-C-1331, "Status of Grain Storage in Developing Countries," was undertaken by the Food and Feed Grain Institute at Kansas State University in conjunction with Contract AID/ta-C-1162 Technical Assistance in Grain Storage, Processing and Marketing and Agribusiness Development.

The text of the report presented here is based on literature reviewed in preparing the appendices which form a part of this report and personal experiences and observations of members of the team of specialists assembled at Kansas State University under Contract AID/ta-C-1162. Since references to the data are cited in the appendices, a separate bibliography is not included. Where reference is made in the text to specific situations, sources are footnoted.

Much of the tedious work of researching publications, reports, and other documents for data was done by Dr. Menter David, Research Assistant and Mr. William E. Pursley, Graduate Research Assistant. Assistance of secretaries in typing and proof-reading the manuscript and the appendix data is also gratefully acknowledged.

We want to especially thank Mr. Dana Dalrymple, AID/PPC/PDA for his assistance in development of this project and in obtaining much valuable data from U. S. Agricultural Attachés in many countries.

STATUS OF GRAIN STORAGE IN DEVELOPING COUNTRIES

Mr. John R. Pedersen

FOOD AND FEED GRAIN INSTITUTE
KANSAS STATE UNIVERSITY
Manhattan, Kansas 66506

INTRODUCTION

In recent years considerable emphasis has been placed on increasing the production of the world's cereal supply to meet the needs of our growing population. High yielding varieties of rice and wheat have been developed and in some areas of the world have materially increased the available food supply. Attendant with the increased food supply is the problem of how and where to store the commodity until it is consumed. Unfortunately, in many situations where production has increased we have not had the foresight to plan ahead and provide the necessary storage facilities. In many of the developing countries storage facilities under normal conditions are inadequate in quantity and quality. Under conditions of stress, such as dramatic increases in production or the current Sahelian catastrophe, the status of the current grain storage situation in developing countries is brought into sharp focus.

The purpose of developing a paper such as this was to focus on the current overall grain storage situation in developing countries. Two goals were in mind. First, as much data as possible was to be assembled on capacity, location and types of grain storage currently available in developing countries throughout the world. Secondly,

storage conditions, problems and deterrents to progress were to be considered.

It has to be acknowledged that a complete cataloging of all existing storage facilities is not presented in this paper. Within the time space spent in gathering information for this paper it was impossible to locate and bring together all of the information that exists on grain storage capacities, locations and types. Much of this information is available only from cereals offices or ministries of agriculture, commerce or statistics within a specific country. Where data does exist, it is often difficult to obtain because it may be considered privileged or strategic information by the holder. In most developing countries the data is incomplete and in many, the data simply does not exist.

Data reported in this paper has been obtained primarily from reports, studies, and papers dealing with various aspects of grain storage in the developing countries. In some cases, data were obtained from official records or statistics. A conclusion drawn during preparation of this paper is that a need exists for a much more thorough and comprehensive effort in compiling data on grain storage capacities, locations and types in developing countries and that such a study should be undertaken by a multilateral international organization.

THE NEED FOR STORAGE

In 1973, 1,223,096,000 M.T. of cereal grains (rye, oats, barley, wheat, rice, maize) were estimated to have been produced world wide.¹⁾ This figure does not include grain sorghum or the oilseeds or pulses. The cereal grains, for the most part, are seasonal with from one to three crops produced each year. The fact that these crops are seasonal and harvested at certain times of the year necessitates holding them for varying lengths of time to provide as uniform a year round supply as possible to consumers. In countries where agriculture is primarily at the subsistence level, farm storage is a necessity. In this type of economy only small quantities of cereal grains are marketed, however, storage for that which is marketed must be provided, usually in urban centers. In many countries the major source for urban population supplies is imports. Storage for these supplies must be provided until delivered to the consumer.

Some of the developing countries have recognized the need for building strategic reserves wherein large quantities of grain may be stored for extended periods of time. Kenya, for instance, implemented approximately 100,000 metric tons of reserve maize storage at Nakuru and Kitale in 1968.²⁾ Just recently President Ford of the United States in his address to the United Nations Assembly recommended the establishment of international food reserves to help alleviate situations such as the food shortage experienced because of the Sahelian drought.

BASIC PROBLEMS IN STORING GRAIN IN DEVELOPING COUNTRIES

To document the need for grain storage is a simple task. Providing storage and technology that is capable of maintaining the quality of cereal grains in the various developing countries is a more complex undertaking.

The Storage Environment - Most of the developing countries are in parts of the world characterized by climates that do not favor the safe storage of grain. High temperatures and humidities exist over extended periods of time making the potential for deterioration due to insects, molds and rodents extremely high. With the best of facilities, storage of grain under tropical conditions is a difficult task.

Education and Technology - In many of the developing countries the individuals responsible for storing grain are not completely aware of the hazards involved. They may not be aware of the physical losses (loss in weight) that occur in grain during storage due to insects, rodents and molds and probably are not aware or concerned with the contamination in the form of urine, excrement, hairs and toxins that can occur as the result of insect, rodent and mold infestations. The presence of insects in grain and rodents in and about storage facilities in many areas is common and probably considered by the individual as one of the necessary evils of grain storage. It probably never occurs to many storing grain that in addition to the physical losses that occur, there are biochemical changes which occur in grain stored under adverse conditions which

materially reduce the nutritional quality of the grain as a food for humans and animals. Loss of vitamins, degradation of carbohydrates, proteins and fats, and production of toxins do occur when grain is improperly stored.

Moisture is probably the most important factor involved in maintaining the quality of grain in storage. High moistures favor the development of insect and mold which in turn cause grain to heat and deteriorate. Low moistures favor the maintenance of good quality grain. This relationship between moisture, grain and the factors of deterioration (insects, molds, etc.) are not completely understood by many. In relatively arid regions of the world considerable quantities of grain have been lost and certain types of storage structures incriminated because persons responsible for storage were unaware of the relationships between moisture and grain and the "management" practices necessary to maintain the grain. This is more likely to occur when grains are imported and received at higher moisture levels than are customarily handled. This is a factor which should be given considerable emphasis with respect to the large quantities of cereal grains being moved into the Sahelian region.

The manner in which grain is "managed" or maintained in storage is a product of the technological knowledge of the individual responsible for storage. Large quantities of cereal grains are lost in the developing countries because of improper storage techniques. Improper stacking of bagged grains can prevent (1) proper inspection of the commodity to determine whether deterioration is occurring, (2) successful fumigation of the commodity if necessary, and (3) natural ventilation in and around the grain to carry off heat which may be produced in grain of marginal moisture contents.

Use of facilities which are unsound from the standpoint of excluding rain, ground moisture, rodents, etc. also leads to the deterioration of considerable quantities of stored grains.

Loss estimates for stored cereal grain are cited anywhere from 5 to 50 percent for many of the developing countries. At best, these figures are "estimates" and in only a few cases are documented studies available to show actual measured losses. We oftentimes tend to observe the more spectacular or dramatic losses that occur and this can lead to "over-estimating." There are proponents also who will argue, from good information, that losses are actually more severe than reported. What this situation indicates, it seems, is that we do not have the reliable type of information needed to accurately assess the losses that occur. Many of the loss surveys that have been conducted are based on information gathered by interview. Considerable opportunity for bias can be injected into surveys of this nature although they provide a fairly expeditious manner of gaining information. More elaborate studies have been designed for actually sampling lots of grain in storage in various types of facilities. These studies are time-consuming and are not entirely without bias. Researchers may be reluctant to report actual observations if the possibility of embarrassing the government or official organizations exists.

These are some of the basic types of problems that can and do exist in storage of grains in developing countries.

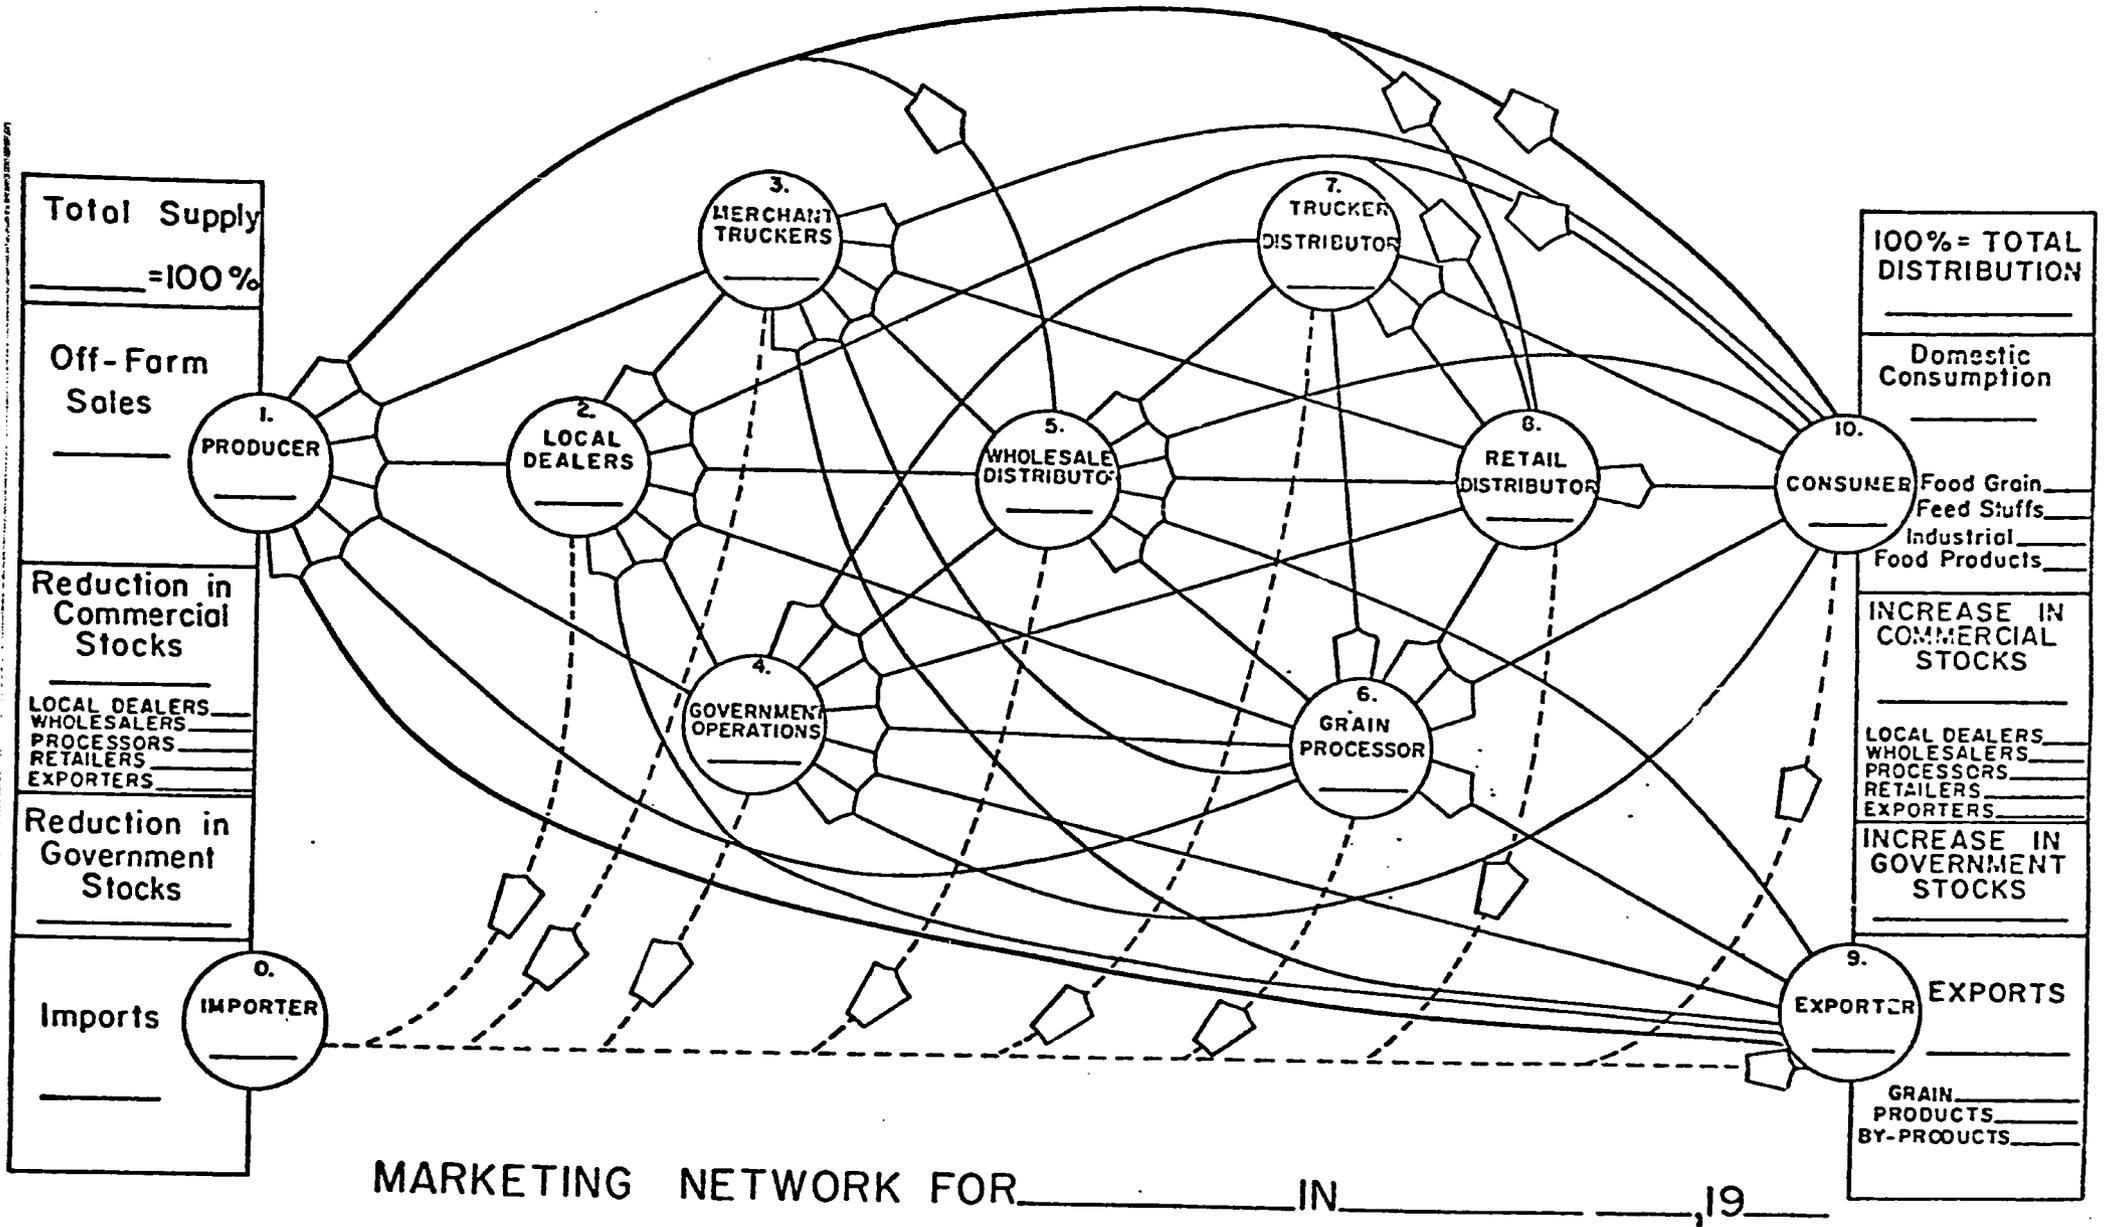

STATUS OF STORAGE AT STAGES IN THE FLOW
OF GRAIN FROM PRODUCER TO CONSUMER

As grain flows from producer to consumer in developing countries there are a multitude of paths which may be followed. Figure 1 is a diagrammatic work sheet which illustrates the complexities which may be encountered in this flow. No two countries seem to have the same marketing pattern or network. Whatever the pathway grain takes from producer to consumer, it is inevitable that it be stored at one or more points in this flow.

Farm Storage - The simplest pathway or situation is where the producer holds grain on the farm for his own consumption. In the developing countries, quantities held on the farm generally range from 70 to 90 percent of the total production. There are exceptions of course where, for instance, all of a farmer's rice may be sold to mills at harvest time and purchased back as needed. However, the general rule is for the major portion of grains produced in developing countries to be stored on farms.

Since the bulk of a country's cereal food supply is stored on the farm it seems ironic that this level of storage has probably received the least emphasis as far as improvement or consideration. This is reflected in the information that is available on farm storage of grain. In compiling the information in the Appendix of this paper, the lack of data on farm storage is quite obvious. Granted, tabulation of data on farm storage capacity is a difficult task because of the large numbers of farms in developing countries and the great diversity in type and size of farm storage facilities.

FIGURE 1. GRAIN MARKETING FLOW PATTERNS.

There are descriptions in the literature of various types of farm storage facilities used in developing countries. In the vast majority of cases, indigenous materials are used in fabricating storage containers. To cite all of the various types of storage containers would create a paper in itself. A few examples will serve to characterize farm storage structures currently in use. In Mexico, maize on the ear and on stalks may be stored cradled in tree or cactus branches. In many Asian countries maize in the ear or rice and sorghum in the head may be suspended by rope or wire in huts over cooking fires. In many African countries small quantities of grain may be stored in dried gourds or other small containers. In Morocco, Jordan and India cereal grain is stored in underground pits. In many African countries ear maize is stacked on platforms and covered with thatch to ward off rain. In many of the developing countries bags of cereal grains are stored within human dwellings. In some areas mud-plastered woven baskets form bins for bulk grain or wooden bins are used, generally elevated on posts to secure the grain. Discarded oil drums have also been placed in service as grain storage containers.

At best, farm storage in most of the developing countries leaves grain supplies vulnerable to insect, rodent and bird depredation and, in those areas where high temperatures and humidities exist, to deterioration due to molds.

Quantity wise, farm storage in developing countries will range from a few hundred kilos to a few tons total.

Research is underway in some areas to develop improved storage facilities for farm use. Use of butyl rubber or plastic containers

strengthened by welded mesh steel is being employed in parts of Africa. This system can produce nearly airtight storage conditions. In Thailand, the Applied Scientific Research Corporation has developed a ferro-cement unit called the "Thailo."¹⁾ Capacity of the unit can range from 2-5 metric tons. In Nepal, a poured concrete unit has been proposed.²⁾ Steel forms are loaned to farmers and construction is accomplished by the farmer and unskilled labor with assistance from a trained individual.

One of the main weaknesses in developing new types of storage facilities for farm use in developing countries has been the lack of economic consideration. Can the farmer afford to buy metal or rubber storage or build the "Thailo" or poured concrete bin on his farm? Costs for these units have been variously estimated at between \$120 and \$200 per unit. No one appears to have asked the question whether the farmer can afford to pay the cost of improved storage. Perhaps he is better off (financially) to absorb the losses he experiences rather than invest in improved storage.

Other instances of farm storage research could be cited, however, the main point of emphasis here is that dollar-wise considerably more effort has been expended in the development of large scale modern storage silos and warehouses than has been devoted to farm storage even though only 10 to 30 percent of the grains produced will ever reach these facilities.

- 1) National Academy of Science (1973) Ferro-cement: Applications in Developing Countries. Washington, D. C. February 1973.
 - 2) Pfalser, Donald F. (1972) Storage Drying and Transportation of Agricultural Commodities MFA Agr. Mktg. Conf. Document No. 12. Agricultural Marketing Conference 21-24 February 1972 Kathmandu, Nepal.

Although there is often an expressed interest, on the part of governments, in the need for improved farm storage it has become apparent that major emphasis is usually directed elsewhere. Most of the studies on farm storage have been conducted and/or financed by multilateral international organizations. Some studies have been conducted by individual countries however, such studies are the exception rather than the rule.

Village Level Storage - Very little information is available on village level storage. Indications are that most of the facilities utilized at the village level do not vary significantly from those on the farm. Many persons consider farm and village level storage as one and the same. Village level storage referred to here is that maintained by local merchants or dealers.

Grain may be held in baskets and/or bags and stored in various types of structures usually shops or storage rooms of indigenous construction. Security from insect, rodent and bird attack is usually comparable to that on the farm.

Cooperative efforts on the part of farmers in a few developing countries have resulted in the development of improved community-type storage facilities, however, this form of cooperation is not widespread.

Village level storage or trading of grains can form the first link in the movement of grain off the farm into major marketing channels. Lack of development of these "first collection points" in the flow of grain from producer to consumer has been one of the major deterrents to the success of some grain stabilization programs. The existence of poor storage facilities at this level is not the main

draw-back, but rather the lack of development of a marketing system, i.e., roads, transport facilities, grading systems, market news, etc. The weakness of this link in the overall flow of grain from producer to consumer is in part responsible for large elevators that have been constructed in developing countries standing empty or not being fully utilized.

It is encouraging to note that there is an increased interest developing in this vital link in the grain storage and marketing system of developing countries - the "first collection point." Countries such as Tunisia, Philippines, and Peru are currently requesting assistance from Kansas State University in this particular area. Serious consideration is being given to the development, design and location of grain collecting stations which will allow reasonable access to the market by farmers. The ultimate success in the development of these collecting centers will be the parallel development of transportation facilities, grading systems, warehousing laws, credit availability and other market associated functions.

Private and Commercial Central Storage - Much of the grain that enters marketing channels in developing countries is currently moved directly from farms or villages to processing plants or to central dealer storage. Truck dealers or processors' agents move out into the producing areas at harvest time and secure grain at the lowest possible prices and move the grain directly into private and/or commercial central storage. Information on capacities and conditions of central or wholesale dealer storage facilities are virtually non-existent. Development of warehousing laws and licensing could do much to consolidate valuable information on this sector of the grain marketing system in developing countries. In most of the developing countries, storage facilities utilized

by this sector of the grain trade consist of warehouses of various types of construction for storage of bagged grain.

Some information does exist on storage at large scale processors such as rice mills, flour mills etc. for some countries. This is generally true in those developing countries which are the more advanced. Most of the grain at the processor level is stored in bags by necessity since grain for the most part is handled throughout the marketing system in bags. Some processors are developing bulk storage at their facilities but, in general, this is the exception rather than the rule. Where grains such as wheat are imported for processing it is more likely that bulk storage and handling equipment will be available especially if the processing facilities are at port locations. A considerable amount of "outside" or uncovered storage may exist at rice and/or flour mills, this depending on climate and whether large grain stocks are maintained at the processing facility.

The quality of storage at private and commercial central storage can range from very poor to excellent and is dependent, in part, on the level of knowledge possessed by those responsible for the grain. In general, one would expect private or commercial dealers in grain to be the most conscious of the cost and importance of maintaining grain in good condition. If the general atmosphere in the grain trade within a developing country is one where good quality grain does not command a premium, storage conditions will probably reflect this attitude. Private dealers who may enter world trade by exporting grains will be more aware of the necessity for maintaining the quality of their commodities in storage.

Government Storage Operations - By far the greatest amount of data available on grain storage capacities and conditions in developing countries is on government storage operations. This is evidenced by the extent and type of information accumulated in the appendices of this paper. This is understandable since government operations are usually documented and these records often become public information. Sources of data presented here, in many instances, have been derived from studies developed in support of various types of government grain storage and marketing programs in which considerable effort has been expended in bringing together the available information on the various aspects of storage.

In most government operations, storage facilities are used in support of grain purchasing, stabilization and/or reserves programs. Depending on the particular country and government operation, storage facilities will range from small, mud warehouses to very elaborate, large-size bulk handling silos. The larger storage facilities (warehouses and/or silos) are generally located in the major consumption centers and at port locations. Government maintained, smaller facilities are usually located at minor consumption centers and are used for either collecting grains or distributing them to the population.

One of the major problems confronting many of the developing countries is the determination of how much, what type and where storage facilities should be located. The presence of large storage facilities standing idle or underutilized in many countries is evidence that proper planning and implementation of storage programs in the past has not been completely successful. Too often the impressiveness of a large silo may overshadow the necessity for a more practical type of facility for the existing situation.

In some instances, construction of large scale grain handling facilities have been justified on the basis that their existence would generate increased production on the part of farmers. Unfortunately, very little or no consideration has been given to how grain will move from the producer to the storage center which may be several kilometers distance. There has been little or no effort given to development of "first collection point" facilities and the supporting functions required for the orderly flow of grain from the producer to major storage centers.

It would appear that government organizations responsible for storage of cereal grains would have access to and utilize the technology that is available to safely store grains. Much of the deterioration and loss of grain that occurs in storage is not a result of poor facilities but rather poor management of the grain in storage. In responding to over 40 requests for technical assistance in grain storage and marketing problems, one of the most common deficiencies our staff members have noted is the lack of knowledge on the basic principles of grain storage. Personnel responsible for storage of cereal grains in many instances are not aware of grain-moisture relationships, basic sanitation practices and storage practices which are paramount to safe storage of grain. This not only applies to government operations, but to all levels of storage. In some instances, the lack of basic knowledge on grains in storage has lead to incrimination of the type of storage for losses rather than the management methods. This is especially true in the case of metal storage facilities.

Reference has been made to idle and/or under-utilized storage facilities in developing countries. In addition to improper planning, a common reason for non-use of these facilities can be attributed to personnel being inadequately

trained in the operation and maintenance of the facilities. In some cases, bulk storage facilities have been "over designed" and provided with equipment much more sophisticated than necessary. This results in increased maintenance requirements and the need for more highly trained operators.

Not all of the problems encountered in government operations in grain storage are technological in the developing countries. In some countries administrative problems may rival the technical problems. It is not uncommon to have more than one department or branch of government involved in the storage of grain. This may involve departments of agriculture, commerce, transportation, etc. or units within departments. Usually the difficulties arise because of lack of communications. Open lines of communication and cooperation should be developed to insure maximum utilization of storage facilities and minimum losses of grain in storage.

Application of Pest Control Measures in Grain Storage - From producer to consumer, no matter what the storage level, there are pests encountered. Reference has already been made to the losses that occur due to the biological factors of deterioration - insects, rodents, birds, and micro-organisms. It is obvious that if the losses which occur could be reduced, this would materially increase our food supply. Reduction of losses through improved storage facilities has been used for justification of the new facilities, however, new facilities in themselves will not prevent losses. In most cases, improved facilities will make reduction of losses easier, but there is a major need for applying an integrated program of pest control measures as part of the grain management program. No one method of pest control in itself is sufficient and a combination of methods must be used.

Where pest control methods are employed in developing countries, major emphasis has been placed on the chemical aspect - insecticides and fumigation. There are a variety of ways in which pests can be controlled other than with pesticides. Use of inspections, application of good sanitation practices, control of the storage environment plus the use of pesticides provides an integrated approach to the pest control problem.

In many developing countries there is little or no attention paid to good housekeeping and sanitation practices in the storage of cereal grains. Some government and private operators have realized the importance of good sanitation, however, generally poor sanitation conditions prevail at all levels of grain storage in developing countries. Improved sanitation would probably be one of the least costly methods for reducing grain losses if the proper information could be disseminated and applied.

At the farm level, the use of chemicals in grain preservation is virtually non-existent. There have been programs in certain countries to promote the use of insecticide dusts of various types but these programs have met with varying degrees of success. Certain unique methods for preserving grain at the farm level are used. Methods of storage such as suspending grains over cooking areas in dwellings to take advantage of the drying effect of the heat would tend to reduce losses due to insects and molds. Unfortunately, the unique practices employed are usually over-shadowed by the poor sanitation conditions which commonly exist under farm situations.

Rodent control on farms is hindered by the fact that many of the storage structures may actually serve as rodent harborage.

Few, if any, attempts are made at controlling pests in the local dealer or merchant facilities. Usually the grain does not remain at this level in the marketing system for extended periods of time. Poor sanitation conditions are the rule rather than the exception at this level of storage.

At private and commercial central storage facilities, the application of pest control measures is dependent on the attitude of the storage management. At this level of storage, where large quantities of grain may be held for varying lengths of time, chemical pesticides are used, primarily in the form of fumigants. The extent of their use is not well documented. Here again, sanitation practices are often poor and storage practices are variable.

In many of the developing countries, processors do not store large quantities of grain for extended periods of time. Most rely on supplies from government or commercial storage operations. Very little emphasis appears to be placed on pest control measures at this point.

Government operations in many of the developing countries are more aware of the need for applying pest control measures than others storing grain. Long term storage of grain reserves has made it a necessity that pest control measures be applied to prevent large scale losses. Here, as in commercial storage, the emphasis has been on the use of chemicals in the form of insecticide dusts and fumigants. Good sanitation and management practices have not been stressed to the fullest extent in most of the developing countries. Certain countries, such as Kenya where large air-tight storage structures have been constructed, are looking to other alternatives of pest control.

AVAILABILITY OF STORAGE WORLDWIDE

A beginning attempt has been made, in the development of this paper, to bring together data on storage capacities, locations and types that exist throughout the world in developing countries. Data that has been accumulated in this effort is assembled in appendices which represent the following four regions of the world - Africa, Asia, Latin America, and Near East-South Asia - and form a part of this report.

Review of data contained in these appendices will indicate the general incompleteness of this type of information that is readily available. It is hoped that this first attempt will stimulate a more in-depth study of the availability of existing storage facilities in the developing countries. This is considered an important undertaking in view of the possibility of the development of international food reserves. An undertaking of this type could most likely be best accomplished by a multilateral international organization.

NEED FOR THE FUTURE

There are many areas of concern which need to be given greater emphasis in the developing countries in the future. Four of the major areas needing primary emphasis are:

LOSSES - It is obvious that losses do occur. The true extent of these losses has not been accurately determined. In view of the importance which is placed on reduction of losses in storage and the importance placed on losses as justification for large scale investment in storage facilities, it would appear that a sound basis for stating the extent of losses should be developed.

FARM STORAGE - Since the major portion of the total grains produced in the developing countries is stored on farms, a greater emphasis should be placed on development of improved farm storage methods and facilities which are economically feasible.

FIRST COLLECTION POINT SYSTEM - That segment of the grain marketing system which will allow the farmer to conveniently deliver excess production into the market system with reasonable assurance of obtaining a fair price for his grain needs to be given increased emphasis. This is a segment of the marketing system which has, in part, been responsible for impeding increased production and the flow of farm grain into the marketing system.

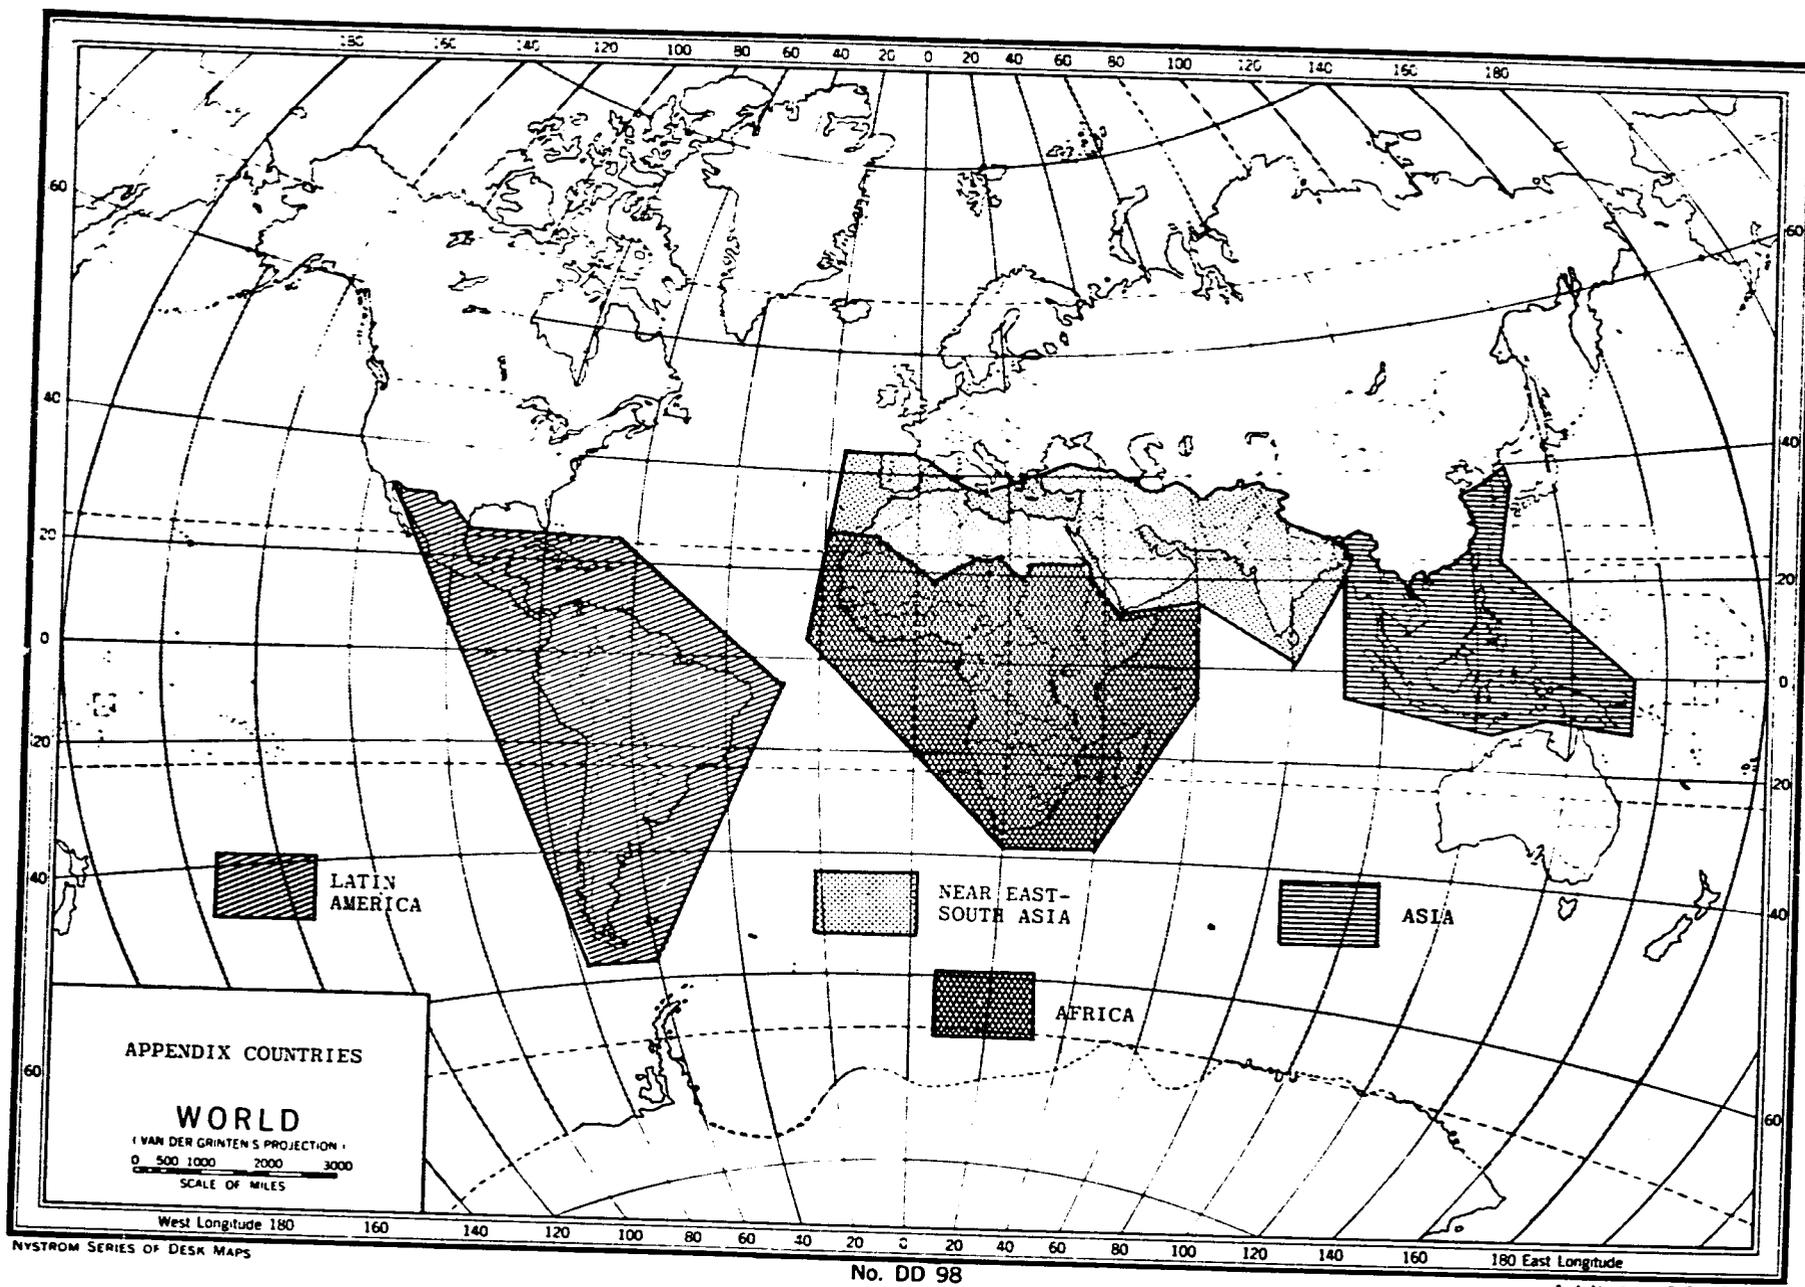

PROJECTION OF NEEDS FOR STORAGE FACILITIES AND FUNCTIONS - Greater emphasis needs to be placed on the systematic evaluation of developing country needs for storage. Sound judgements, based on evaluation of all factors bearing on grain storage and marketing, must be made in recommending future needs for storage facilities and functions. Thorough evaluation and planning should be directed at reducing the possibility of building grain storage facilities which become idle "monuments."

SUMMARY

As stated, the main purpose of this undertaking was to assemble as much information as possible on the capacity, location and types of grain storage currently available in developing countries throughout the world and to consider the storage conditions, problems, and deterrents to progress.

One of the main conclusions drawn from the effort reported here is that data on storage capacities and locations for many of the developing countries is not readily available. In some cases it is probably non-existent. It is recommended that in view of the potential for development of worldwide grain reserves a more complete study be undertaken by a multilateral international organization.

In general, improvement is needed in grain storage at all levels in the movement of grains from the producer to the consumer--farm, village, commercial, processor and government. Problems encountered in storing grains safely are of a biological, economical and political nature. Probably the greatest deterrent to safe storage of grains in developing countries is the lack of knowledge of the factors causing deterioration of grain and proper "management" of the grain.

THE APPENDICES

The bulk of this report is made up of a series of appendices representing four areas of the world--AFRICA, ASIA, LATIN AMERICA and NEAR EAST-SOUTH ASIA as shown on the map on the opposite page.

The Appendices are color coded as follows:

AFRICA	-Buff
ASIA	-Blue
LATIN AMERICA	-Yellow
NEAR EAST-SOUTH ASIA	-Green

Within each Appendix, countries are indexed alphabetically and numbered. Countries for which no data on storage capacities was obtained, we indicated as "no data" in the index. Where data was obtained, it is presented in the designated appendix.

Sources of data are indicated as completely as possible in each individual appendix.

BOTSWANA

No data are presented here for farm or other grain storage capacities. Any bulk storage of grain for Botswana would generally be handled in South Africa.¹⁾

1) Personal Communication, U.S. Agricultural Attaché, Pretoria, February 19, 1975.

CHAD

No data is available on farm storage methods or facilities.

Data included, on public and private storage facilities, is the most recent information available.

Additional information on Chad can be found in Africa Appendix 42 Entente States.

PUBLIC AND PRIVATE STORAGE FACILITIES IN CHAD

Prefecture	Locality	Type of Storage	Tonnage	Remarks
SALAMAT	Am-Timan	Silo	100 t	
	Aboudeia	Storehouse	300 t

DAHOMY

See Entente States.

ETHIOPIA

The available capacity of the Ethiopian Grain Corporation (EGC) in November 1974 was reported as 62,450 M.T. (See attached table). Bulk silo capacity owned by EGC totals 29,000 M.T.; a 20,000 M.T. silo at Addis Ababa consisting of a double row of 500 M.T. bolted steel plate bins, a central headhouse with cleaners and scales, fully mechanized and with temperature measuring equipment; and 9,000 M.T. at seven sites in groups of 1,000 or 2,000 M.T. country silos consisting of 200 M.T. bolted corrugated metal bins.

Even though bulk storage facilities exist, all transport of grain is in bags.¹⁾

Warehouses owned by EGC are small, simple structures with corrugated sheet metal walls and roofs on a wooden frame of eucalyptus poles and concrete or stone slab floors. Similar type structures are being erected for the Extension and Project Implementation Department relief storage. Warehouses leased by EGC are of similar construction. Effective capacities for long term storage are about 70 percent of stated capacities.¹⁾

From a survey conducted in 1971-72, the private warehouse capacity is estimated at approximately 340,000 M.T.²⁾ and is located as follows:²⁾

<u>Location</u>	<u>No. Units</u>	<u>Capacity</u>
Addis Ababa	50	105,000 M.T.
Asmara	40	100,000 M.T.
Nazareth	80	80,000 M.T.
Other Country Marketing Centers (25-50 M.T. Size)		55,000 M.T.

Capacities and location of EGC, AMC and Relief storage facilities are shown in the accompanying tables and maps.

GAMBIA

No data available on storage capacity in Gambia.

Paddy rice is stored on the farm either on the head (unthreshed) or threshed in bags in dwelling houses.

GHANA

Farm storage in Ghana is principally of three traditional types: 1) the "Ewe Barn," a raised circular platform on which cobs are built up to form a cylinder and covered with thatch, (2) the "Achanti Crib," a raised rectangular structure constructed of wood or bamboo and roofed with thatch, and (3) the "Pole Type Storage," whereby bunches of cobs are hung from horizontal poles.

Burnt brick, concrete or aluminum silos are used in larger towns, government-controlled agricultural organizations and large scale private farms. Aluminum silos of 10 to 250 M.T. capacity are most popular.

Warehouse storage of maize in bags is widely practiced also.

Large scale government bulk storage in the form of modern concrete silos has been promoted in the past 5 years. Eight major facilities were in various stages of completion in 1969 as indicated below:

<u>LOCATION</u>	<u>CAPACITY</u>	<u>STAGE OF COMPLETION</u>
Accra	10,000 M.T.	Near Complete
Kumasi	5,000	Contracted
Takoradi	5,000	Near Complete
Cape Coast	5,000	Platform Finished
Tamale	5,000	Platform Finished
Ho	5,000	Near Complete
Sunyani	5,000	Contracted
Wa	5,000/45,000 M.T.	Platform Finished

In addition another 100,000 M.T. capacity exists at Terna that could be used for grain.¹⁾

More data on bulk and warehouse storage facilities in Ghana may be found in Africa Appendix 42, Entente States.

1) AID (1969) "Grain Stabilization Study - The Entente States and Ghana" Economic and Engineering Study. Prepared by Weitz-Hettelsater Engineers, Inc.

IVORY COAST

No information is included here on farm storage. Data on bulk grain storage and warehouse storage is included in the "Entente States," Africa Appendix 42.

The "Grande Moulin de'Abidjan" located in Abidjan is privately owned and has a capacity of 30,000 M.T. Four major rice mills have a total of 20,200 M.T. capacity and government controlled warehouse a total of 18,000 M.T. capacity.¹⁾

1) AID (1969) "Grain Stabilization Study - The Entente States and Ghana" Economic and Engineering Study. Prepared by Weitz-Hettelsater Engineers, Inc.

KENYA

No information is presented here on small farm storage of grains.

On large farms, maize on the cob may be stored in cribs with open type construction to allow air ventilation for drying. A greater proportion of the maize is stored in bags. Standard bag storage facilities are of poor construction and condition. Large numbers of farms with some sort of grain silos for storing bulk grain do exist.¹⁾

In addition to data in the accompanying table, the Maize and Produce Board in Kenya has constructed a total of 70 air-tight "Cyprus" bins; 40 at Kitale and 30 at Nakuru. A total capacity of 1,000,000 200-pound bags of corn (capacity 100,000 M.T.) as a long term strategic reserve can be accommodated in these bins.²⁾

The Maize and Produce Board in 1972/73 entered into contracts for the construction of five (5) new stores (two at Sagana, one each at Nairobi, Webuye and Moi's Bridge), and major redevelopment of the Nairobi depot. These new stores will provide additional storage capacity of 500,000 bags, giving a total maize capacity of about 4,000,000 bags.³⁾

Wheat storage capacity (1972-73) in Kenya is shown in Table 2. The total capacity of 1,107,500 x 90 Kilo Bags is equivalent to 99,675 M.T. Bulk storage capacity was 14,310 M.T.⁴⁾

LESOTHO

No data are presented here for farm or other grain storage capacities. Any bulk storage of grain for Lesotho would generally be handled in South Africa.¹⁾

1) Personal Communication, U.S. Agricultural Attaché, Pretoria, February 19, 1975.

LIBERIA

No data is presented here on farm storage. The Freeport in Monrovia has no facilities for handling bulk shipments of grain and the capacity of small flat warehouses is not known. The Mesu Feed Mill in Monrovia has only small storage. The Seaboard Allied elevator in Buchanan has a capacity of 7,500 M.T.¹⁾

¹⁾ Personal communication, U.S. Agricultural Attaché, March 6, 1975.

MALI

No data is available on farm storage capacities or methods.

Data presented here reflects storage facilities operated and/
or utilized by the government storage organization.

NIGER

Many of the facilities in Niger are small capacity village level structures left over from the colonial system which has a "forced storage system." After independence, farmers went back to traditional on-farm storage. No data or information is presented here on farm storage.

Data on bulk storage and warehouse capacities are included in Africa Appendix 42 Entente States.

NIGERIA

Except for small quantities stored by the Government agencies as famine reserves, most of the production is stored by farmers and traders.

The Nigerian Stored Products Research Institute is probably one of the most active national organizations promoting improved grain storage in Africa. The Institute for Agricultural Research at Samaru (closely associated with Ahmadu Bello University) has concentrated on improved methods of farm storage, especially for northern Nigeria. Current work deals with modification of flask-shaped mud structures with thatched roofs and capacities of 100 to 1,000 pounds. Sorghum is stored in the head in these "rumbu" and cowpeas in the pod. Structurally, they cannot withstand pressures of bulk grain if filled completely. Some farmers are said to have as many as 20 "rumbu" outside the home.

Traditionally small quantities of maize are stored in overhead areas of dwellings in the Western State of Nigeria. A cooperative experiment in this area initiated with two 20-ton capacity aluminum silos has grown to a present fifteen silos with 2,400 M.T. capacity (1971). There are proposals to build 15 more silos for corn and 11 for rice in the future.¹⁾

Although there is no detailed information available on grain storage facility capacity in Nigeria, it is estimated that the State Governments have a combined capacity of 90,000 M.T. Data is not available on individual State storage capacities.

The Federal Military Government has indicated that it plans to expand grain storage facilities to 250,000 M.T. during the Development Plan, 1975-80.

Private grain storage facilities, owned by wheat millers, are estimated at 59,000 M.T. and located as follows:²⁾

<u>Location</u>	<u>Capacity</u>
Lagos	22,000 M.T.
Sapele	15,000
Port Harcourt	16,000
Calabar	6,000

Groundnuts are stored in large pyramids each consisting of approximately 1,000 tons in bags. At Kano there are depots storing groundnuts in about 100 pyramids.³⁾

 - 3) Krishnamurthy, K. (1971) Improvement of Storage of Food Grains and Commercial Crops in Nigeria. Bull. Grain Tech. 9(1):40-45.

SENEGAL

Small mud huts are the common type of storage facility in the countryside. Two mills in Senegal have storage capacities as follows:¹⁾

Les Grands Moulins de Dakar	about 12,000 M.T.
Moulins Sentinac	less than 5,000 M.T.

¹⁾ Personal communication, U.S. Agricultural Attaché, March 6, 1975.

SIERRA LEONE

No data is presented here on capacity of farm or government storage in Sierra Leone. A commercial milling company is reported to have an elevator with capacity of 7,500 metric tons bulk storage.¹⁾

¹⁾ Personal communication, U. S. Agricultural Attaché, (Liberia)
March 6, 1975.

SOMALIA

Grain sorghum and maize are the principal grain crops. Approximately 50 percent of the production is estimated to be stored on farms. In the southern area almost all farm and some merchant storage is in underground pits. Some grain is stored in bags also, bag stored being the only means where underground storage is not suitable. Farm pits usually hold between 5 and 25 M.T. while those of merchants may have 100 M.T. capacity. ¹⁾

In 1964 an FAO report indicated that government grain storage facilities consisting of upright concrete, masonry and metal silos totalling 2,100 M.T. existed at seven locations and 2,400 M.T. sack storage capacity existed at four locations. None of the government storage facilities were in use and had not been used since 1958. No agency had taken up grain storage, management or maintenance and facilities are slowly deteriorating. Type and location of storage facilities are shown in the accompanying tables. ²⁾

REPUBLIC OF SOUTH AFRICA

No data is presented here for farm or village-level grain storage.

The government of the Republic of South Africa began making loans available for construction of grain silos as early as 1952. Initial rate of construction was very slow and up to 1965, only 1,284,000 tons capacity had been erected. As a result of the change-over to combine-harvesting of maize, the "Maize Board" requested increased government loans to cooperatives for new storage. From time to time the government has also made loans available to millers and agents other than cooperatives. As a result of increased government loan funds, bulk grain storage in 1974 has nearly doubled since 1970. Government loans accounted for 68.7 percent of new construction with 31.3 percent financed from other sources.¹⁾

Although information presented in the table on the following page covers only about half of the Republic of South Africa, bulk storage facilities not mentioned here would be considered insignificant (see map, page 59).²⁾

SWAZILAND

No data are presented here on farm or other grain storage capacities. Any bulk storage of grain for Swaziland would generally be handled in South Africa.¹⁾

1) Personal Communication, U.S. Agricultural Attaché, Pretoria, February 19, 1975.

TANZANIA

A recent study¹⁾ of traditional storage structures in the Iringa Region indicated that 24 percent had capacities ranging from 0-9 bags (90 Kg each) and 71 percent had capacities of 10-21 bags. Data was based on a small sample survey.

Most of the bulk storage of crops in Tanzania is presently being handled by the National Milling Corporation (NMC). Products handled are mainly grains and seed-beans. These products are primarily stored in godowns and in cases where storage facilities are inadequate, the produce is stored in movable tailored plastics. The total storage capacity of NMC is approximately 207,700 metric tons and is distributed as shown in the accompanying table.¹⁾

¹⁾Mphuru, A. N., M. A. M. Maro and I. A. Odero-Ogwel (1974) Traditional Storage of Food Grains in Tanzania - With particular reference to The Storage of Maize in Iringa and Morogoro Regions. University of Dar es Salaam, Faculty of Agriculture and Forestry, Morogoro, August 1974. 57 pg.

TOGO

No information is presented here on farm storage.

One metal silo is located at Lama-Kara and has 50 M.T. capacity operated by SORAD, plus 10,000 M.T. warehouse capacity at Lome.

Plans to construct 10 small warehouses (150 M.T. capacity each) in the Savanna district in central and northern Togo were in process in 1969.

See Africa Appendix 42, Entente States.

UPPER VOLTA

Many of the facilities indicated on the following pages for Upper Volta are small capacity, village level structures left over from the Central Colonial system which required a "forced storage system." After independence, farmers reverted to storing grain in their own facilities. The facilities have been unused and are reported to be in various stages of disrepair.¹⁾

Data on bulk storage capacities included in the accompanying table is also included in the "Entente States" section, Africa Appendix 42 .

1) AID (1969) "Grain Stabilization Study - The Entente States and Ghana" Economic and Engineering Study Prepared by Weitz-Hettelsater Engineers, Inc.

	GRAND TOTAL	15,115,651

See also: The total of approximately 15,000 MT of storage capacity is available throughout the country in some 299 existing structures of unknown quality.

Reference: Ackels, A.G., Anderson, J.L., Brinkman, G. & Sorenson, L.O., 1970, "A Study and Plan for Regional Grain Stabilization in West Africa," Food Grain Drying, Storage, Handling and Transportation, Report No. 21, Food and Food Grain Institute, Kansas State University.

ZAIRE

No data are available on total capacity of producer storage. Producers commonly store quantities of maize they will need for food and seed in the ear on rafters in their homes over the cooking area. Maize to be sold in the market, to dealers or the government is left in the field on stalks or stored on thatch-covered platforms near the field until it is sold. Maize grain and peanuts may be stored in baskets either suspended inside or outside of the huts.^{1) 3)}

Prior to independence in 1960, large enterprises were said to have storage facilities on plantations, at factories and at transfer points along transport routes.¹⁾ Some of these facilities still exist and are still in use, however, there is no accurate estimate of such storage.³⁾ Many of the facilities have been taken over by the government and at present, storage functions seem to be distributed among several agencies.

A National Office of Cereals (ONACER) was established in 1974, however, this organization owns or controls facilities for only small quantities of storage at present. It has been recommended that ONACER establish ten grain collection stations with warehouse sack storage capacity of 20,000 M.T. total in 1976 with expansion to 100,000 M.T. by 1985.³⁾ These collection stations would serve to move grain from producer areas to consuming and processing centers in Kinshasa, Lubumbashi, and other consumption centers.

Some bulk storage for grain does exist at a few locations in Zaire.
 Rough estimates indicate the following bulk storage capacities:²⁾³⁾

<u>Location</u>	<u>Facility</u>	<u>Capacity</u>
Matadi	Midema Flour Mill	14,000 M.T.
Kinshasa	OZAC	15,000 M.T.
Likasi	Gecamine Mills	(est.) 6,000 M.T.

ZAMBIA

Since 1967, a variety of grain storage facilities have been constructed in Zambia. There are four methods of grain storage in Zambia - (1) Bulk - in silos; (2) Bag - in covered sheds; (3) Bag - in sheds with roofs, no sides; and (4) Bag - on hardstandings under P. V. C. tarps.

Total storage capacity, excluding sheds which have been taken over by fertilizer, stood at 7,735,500 bags as of October 1974.

The accompanying table indicates types, capacities and location of storage facilities added since 1967.

In addition to storage indicated above, two 250 bag capacity silos were to be completed July 31, 1973 but as of October 1974, the National Agricultural Marketing Board had not accepted them.¹⁾

c/ Data derived from Table 6.7. Estimated storage capacity of 100 tons at each rice mill.

d/ Data derived from Table 6.7. Estimated storage capacity of 10 tons at each huller and as estimated storage capacity of 3 tons at each water wheel mill.

e/ Based on the assumption that the storage not reported in a province is approximated equal to the percent of grain marketed (25 percent) to supply one month's consumption, multiplied by 1.5 to convert rice to gabah. Example: Atjeh - From Table 8.3 the 1970 consumption is 290,000 tons of rice. Thus (290,000) (0.25) (1/12) (1.5) 9.1 thousand tons of gabah storage capacity equivalent. In Djakarta 100 percent of the grain is marketed.

f/ Data not available by provinces.

KOREA

Warehouse capacities reported in data presented here is in "straw bags." It is estimated that each straw bag has an approximate capacity of 54 Kg of rice. Using this assumption the total warehouse capacity for Korea would be approximately 533,167 metric tons.

MALAYSIA/SINGAPORE

In general, there are three categories of storage in Malaysia: farm storage, small commercial stores, and government, large cooperative and commercial godowns. The various types of farm storage range in size from 350 lbs. to 32,000 lbs., are characteristic for an area and are primarily constructed of wood, bamboo or tree bark. Small commercial stores hold rice in 220 lb. sacks stacked 12-14 bags high in ground-floor shops of brick or cement construction. Capacities range from 400-600 sacks. Government, cooperative and commercial godowns of concrete or brick masonry or corrugated metal have wood, concrete or padi husk floors. Average capacity of godowns is 5,000 metric tons (sack storage) with a few of 150,000 M.T. capacity.¹⁾

It is estimated that approximately 40 percent of 1.1 million long tons of locally produced rice is consumed at the farm level and that the remaining 60 percent is bought by the National Padi and Rice Authority and the private millers in roughly equal portions.²⁾

Singapore's rice storage facilities are estimated at 200,00 tons with the private sector accounting for 150,000 tons and the public sector 50,000 tons. If necessary Singapore can easily expand its rice storage capacity substantially since approximately 5 square miles of warehousing facilities exist here. Nearly all of the "godowns" are of steel and corrugated metal with concrete floors.²⁾

Capacities of modern wheat storage silos for Malaysia/Singapore are shown in the accompanying table.²⁾

**MALAYSIA/SINGAPORE
WHEAT STORAGE**

<u>Peninsular Malaysia</u>	<u>Silo Capacity</u>
United Malayan Flour Mills Bhd. Butterworth, Province Wellesley, Penang	16,000 long tons
Malayan Flour Mills Bhd. Lumut, Perak	30,000

PHILIPPINES

Data included here indicates that approximately 18 percent of warehousing capacity is operated by the Farmer's Cooperative Marketing Association (FACOMA), 8 percent by the Rice and Corn Administration (RCA) and 74 percent is privately owned. In general, the warehouses in use have concrete floors and walls of corrugated metal or concrete blocks and corrugated metal roofs. Indications are that most of the warehouses are in relatively poor condition from the standpoint of maintenance and sanitation.

Bulk silo storage facilities are owned and operated by private grain processors (213,700 M.T.) and government agencies (15,050 M.T.). The relatively new privately owned silos are efficiently and effectively operated. The government silos are in need of rehabilitation.

Recent data supplied by the National Grain Authority¹⁾ indicates the grain storage capacities for the Philippines as shown in Table 3.

¹⁾ National Grains Authority, January 13, 1975.

(Data from National Grains Authority)

TAIWAN

In addition to the data presented in the accompanying table, a recent report supplied by the U.S. Agricultural Attache (February 28, 1975) discussing port site and grain processing storage indicated the following:

Port of Keelung (located in northern part of Taiwan)

The port facility here has a storage capacity of 50,500 M.T. and is equipped with one (1) unloading units rated at 200 M.T./hour and two (2) units rated at 100 M.T./hour.

Port of Taichung (located in central part of Taiwan)

A new facility is being built with expected use in 1977. Capacity of this unit is unknown.

Port of Kaoshiung (located in southern part of Taiwan)

One storage facility of 40,000 M.T. capacity for barley and wheat is equipped with two (2) unloading units rated at 200 M.T./hour each. A second facility for handling soybeans and corn has storage capacity of 15,000 M.T. A third facility under construction will have 40,000 M.T. capacity and a fourth facility of 60,000 M.T. capacity is to be constructed.

Grain storage facilities at grain processing facilities in Taiwan were indicated as follows:

Oat Mills - Storage capacity in metric tons.

	<u>Bulk</u>	<u>Bag</u>	<u>Total</u>
In use	126,250	95,572	221,822
Under construction	<u>40,750</u>	<u>7,560</u>	<u>48,310</u>

¹⁾ Personal communication, U. S. Agricultural Attaché, February 28, 1975. Data from Grain and Feeds Development Foundation.

THAILAND

There is only limited information on the grain storage capacity of Thailand. A large portion of the grain is stored in the millions of producers farm homes and there is no estimate of this capacity.

About 90 percent or more of the total known storage capacity is for flat storage of bagged grains. Ten percent or less of the storage is in the form of bulk or silo storage.

Grain storage in Thailand is divided into two main categories, Rice and Coarse Grains, with the following estimated storage capacities:

COMMERCIAL GRAIN STORAGE

	Paddy (Rough Rice)	Milled Rice	Corn & Sorghum
	----- (X1,000 MT) -----		
1. Domestic			
Dealer (Middle-man)	1,000,000	--	--
Rice Mills	3,000,000	600,000	
Up-Country Storage	--	--	500,000
2. Exporter	1,000,000	500,000	600,000
	<hr/>	<hr/>	<hr/>
TOTAL	5,000,000	1,100,000	1,100,000

Reference: Personal Communication, U. S. Agricultural Attaché,
February 19, 1975.

SOUTH VIETNAM

No data on farm storage capacities are given here. It is estimated, however, that roughly 73 percent of rice produced remains on farms for home consumption.

ARGENTINA

Although Argentina is not generally included among the developing countries, data on storage capacities was available and is included here for reference and to illustrate the type of information that would be desirable in a report such as this.

Data from two sources are included. Fienup (1969) includes both "official" and "private" capacities, whereas, the more detailed data of Agri-Research (1967) includes only "official" storage.

ARGENTINA: Capacity of Grain Storage in Official and Private Installations
(Thousands of metric tons)

Description	1954	1964	1965	1966
<u>Official port installations</u>	-	<u>3,092</u>	<u>3,403</u>	<u>3,194</u>
Elevators	-	925	999	985

BOLIVIA

Storage facilities in Bolivia are basically controlled by business firms. The exception is 26,700 M.T. of silo storage with drying facilities being constructed at Santa Cruz by the Government Rice Agency, ENA. Government agencies and cooperatives lease grain product warehouse storage as needed, although presently it is mainly for milled rice storage.

Ministry of Agriculture (MAG) has not compiled an estimate of on-farm and off-farm grain storage capacity in Bolivia. Until this is done, only figures made available by industry groups serve to provide estimates of locations and capacities of grain storage facilities.

WHEAT: Wheat storage facilities are located at the flour mills in 7 locations. Total capacity is estimated at 37,500 M.T. About 30,000 M.T. is warehouse type with the remainder, bulk storage.

CORN: The only known storage capacity for corn is at the cooperative, San Jose Obrero, which has 5 silos of about 260 M.T. each for a total of 1,300 M.T.

BARLEY: Storage of barley is primarily at the breweries. Estimated total storage capacity of the Bolivian breweries is 7,500 M.T. of warehouse type storage.

RICE: Rice storage will be located at Buena Vista and Santa Cruz. It will consist of 26,700 M.T. of silos with drying equipment. The facility is expected to be completed by March 1974.

Other rice storage is located at rice mills. It was estimated at 20 days operating capacity or a total of 7,500 M.T. of warehouse type.

SOYBEANS: The Guzman plant in Cochabamba has adobe walls, tin roof, flat storage of about 1,000 M.T.

BRAZIL

Data for silo and warehouse storage capacities are included from two sources. Overall storage for the country as shown in the accompanying table does not necessarily reflect "grain storage" entirely. It should be pointed out that much of the storage is not used or available for cereal products. A number of other agricultural products, primarily coffee (3 million tons), plus non-agricultural and industrial products are also stored in the warehouses.

Additional data is presented for northeast Brazil. There are some obvious discrepancies between the two sets of data for northeast Brazil even though data were presumably collected at about the same time (1961-62). A map shows the location of storage facilities in northeast Brazil.

Farm storage data are not included here. In 1965 a campaign was started in south-western Brazil to encourage the erection of about 50,000 wire-netting cribs (7-8 tons capacity) for storage of maize grown by small producers. This type of storage has not proven entirely satisfactory because of losses due to insects even when grain is treated with pesticides.

In northeast Brazil small capacity metal cylinders were subsidized by the government for farm storage. Approximately 8-16 bushels of grain are stored in these units and their construction makes them virtually

airtight units. No information on the success or failure of these units is available.¹⁾

Recent correspondence has indicated that Companhia Brasileira de Armazenamento (CIBRAZEM) has undertaken a full census on storage capacity in Brazil with a target date for completion in March 1975.²⁾

NORTHEAST BRAZIL

Storage Facilities

SUDENE reports (§) that there are in the Northeast at present, completed or about to be completed, 34 units for storage with a capacity of some 134,000 tons. These units, financed by the government, are located in the food producing areas. The priority program for new construction, which SUDENE reports is at the moment limited to warehouses, raises the total units to 90 and the total capacity to 415 thousand tons so that the minimum needs of each state can be met as follows:

<u>State</u>	<u>No. of Units</u>	<u>Capacity in Tons</u>
Maranhão	6	46,000
Piauí	8	29,000 ^{1/}
Ceará	10	49,000 ^{1/}
Rio Grande do Norte	6	40,000 ^{1/}
Paraíba	10	52,000 ^{1/}
Pernambuco	11	66,000 ^{2/}
Alagoas	8 ^{3/}	26,000 ^{1/}
Sergipe	6	13,000 ^{1/}
Bahia	25	94,000 ^{4/}

1/ additional storage amounting to a total of 45,000 tons completed of about to be completed at these 6 locations.

2/ all units already completed.

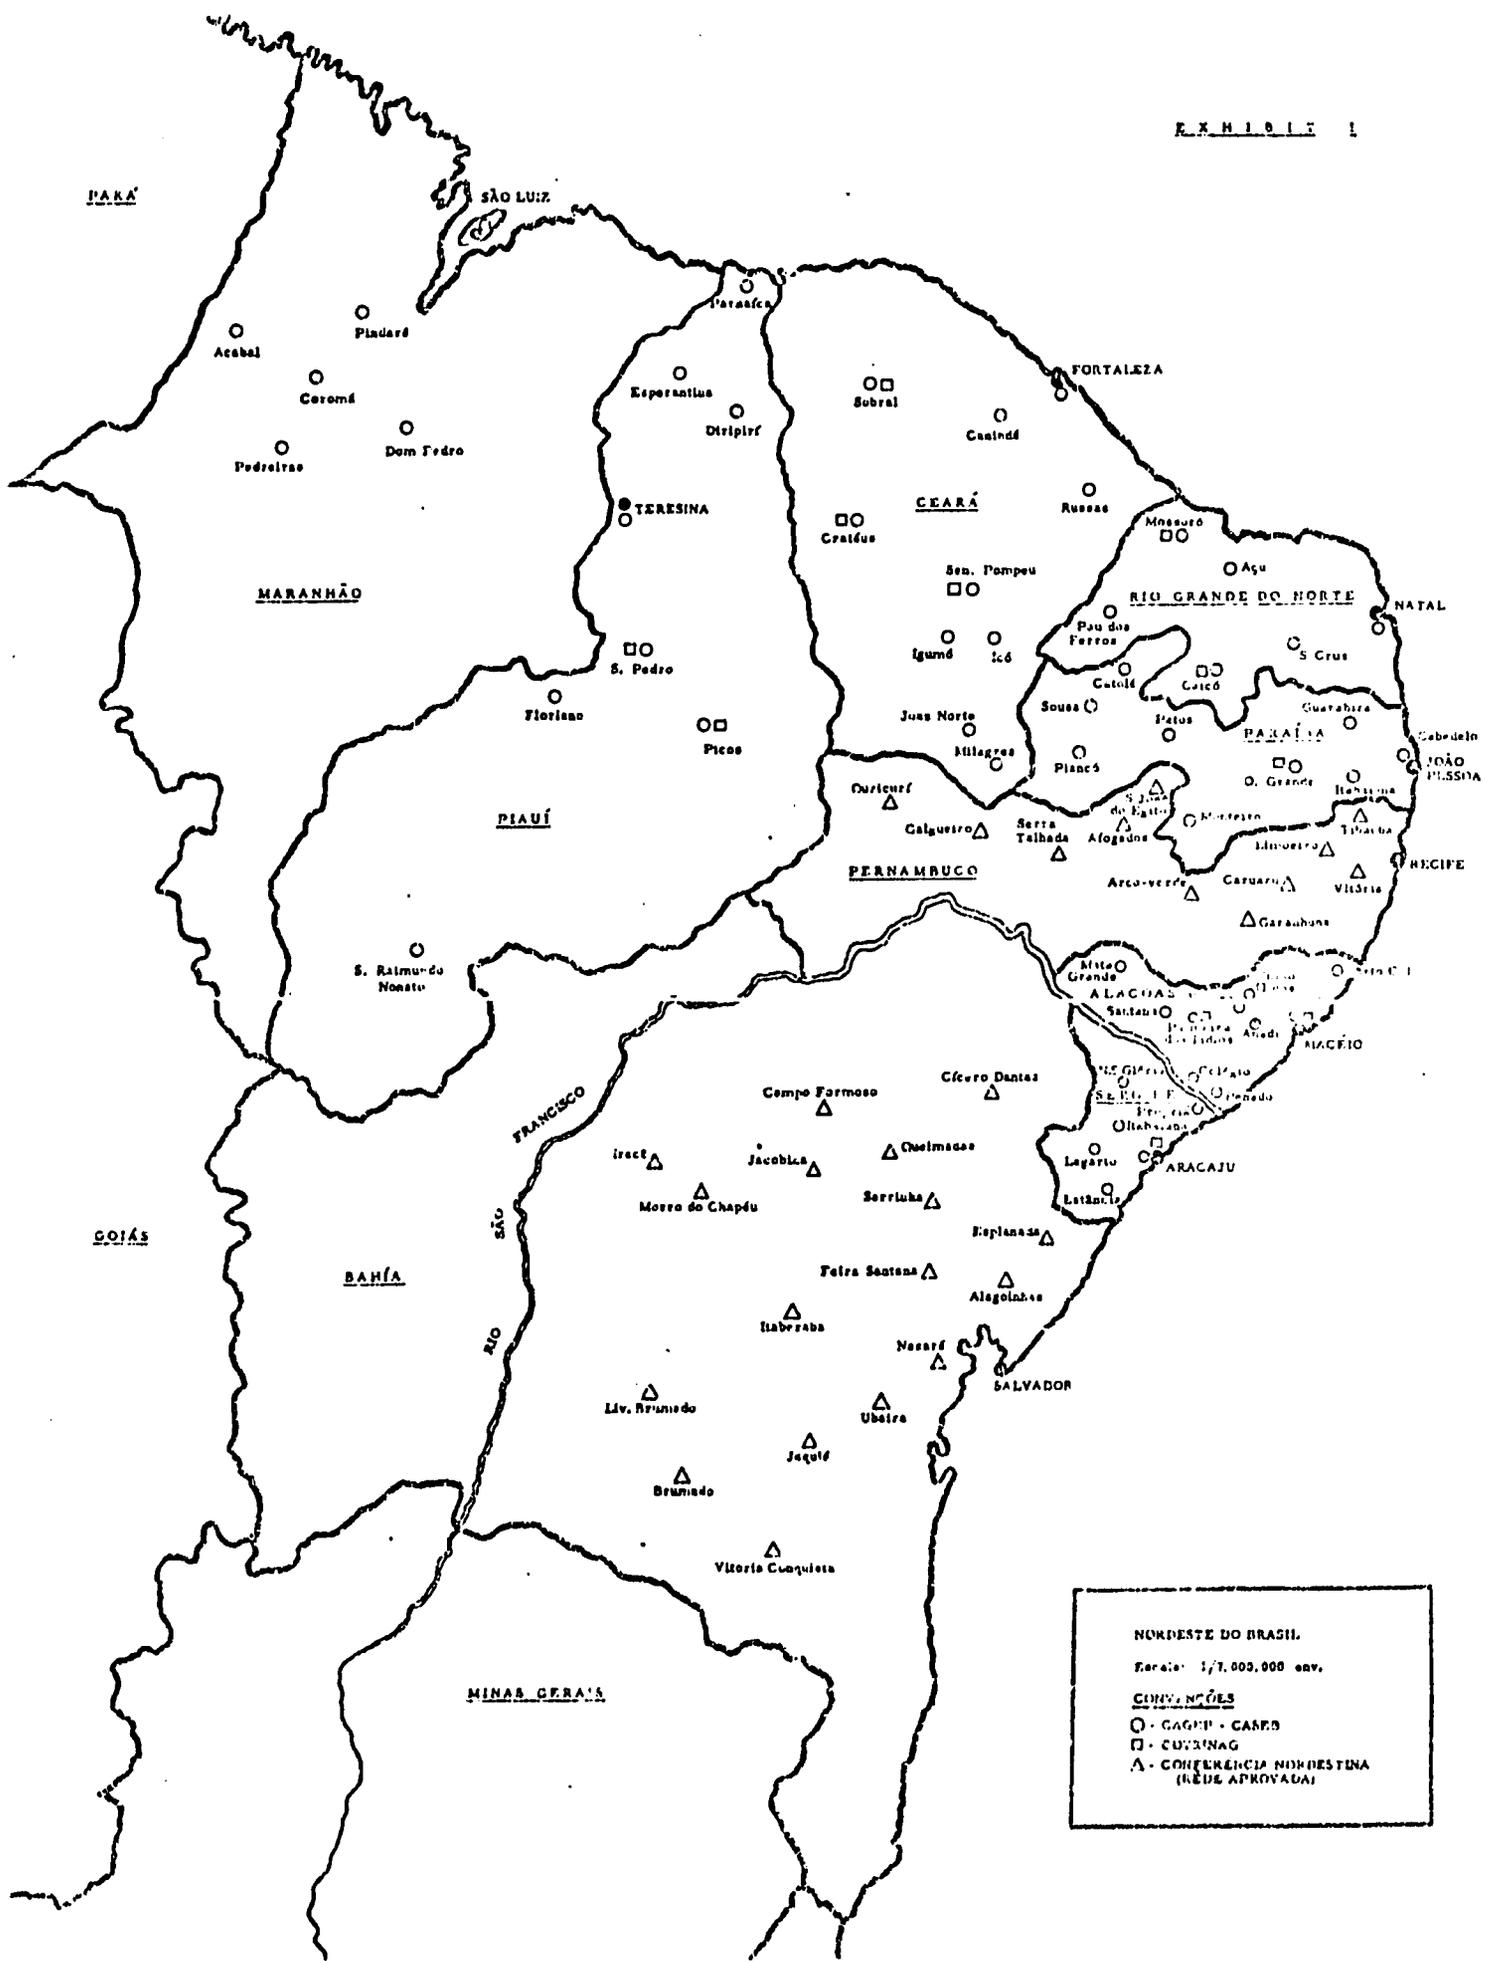

3/ the two units which have been provided for, were consolidated in one thus lowering the total from ten to eight.

4/ total storage capacity for 23,000 tons completed to date.

The maps in Exhibit I show the location of the storage facilities in N.E. Brazil with the exception of Bahia where 17 locations are shown instead of 25.

COLOMBIA

No data on farm storage facilities or capacities are presented here.

Likewise information on capacity of grain elevators owned by flour mills, feed mills and breweries is not included here.

There are two government corporations which have responsibility for storage of grain--IDEMA and INAGRARIO. Data presented in the accompanying tables is for storage facilities operated by IDEMA. Comparable information for INAGRARIO is not included.

The Superintendencia Bancaria (Bogota) has indicated that there are over 2,000 private general warehouses in Colombia with a total storage area of 2,462,119 square meters and a volume of 12,530,127 cubic meters. The total capacity of these warehouses, if utilized for grain storage, would be approximately 6,300,000 metric tons, however, the amount of private general warehouse space actually used for grain storage is not known.¹⁾

¹⁾ Personal correspondence, Superintendencia Bancaria (Bogota) to U.S. Agricultural Attaché, Bogota, June 9, 1975.

DOMINICAN REPUBLIC

No data on farm or commercial storage is presented here. Farm storage is probably insignificant in that paddy rice is generally sold directly to the rice mills from the field. Some maize may be stored on farms.

Data presented in the accompanying table reflects storage facilities controlled by the government. Storage warehouses indicated as "under construction" are believed to have been completed. Whether or not the total number of facilities projected were completed is not known. Since data in the accompanying table were published at least three bulk storage silos operated by the Ministry of Agriculture have been completed at the following locations:

<u>Location</u>	<u>Capacity</u>
La Vega	11,300 M.T.
Santiago	6,800 M.T.
San Juan	6,800 M.T.

ECUADOR

No data for farm storage or total grain storage for Ecuador are presented here.

Rice mill storage capacities are shown in data presented here. Storage at rice mills usually consists of two general types: (1) open shelters constructed of bamboo with bamboo mats for floors or (2) concrete rectangular bins under wood or thatched roofs.

- In Storage Plant No. 1 the warehouses for storage of grain No. 1 as occupied by the Department of Packaging and Distribution and Warehouse No. 3 for materials
- In Storage Plant No. 2, warehouse No. 7 of the Cotton Co-op is in very poor condition, and cannot be used for grain storage and the remainder of the same cooperative have leaks, but not as bad as No. 7. In addition, warehouse No. 9 of the Cotton Co-op in order to be used must have the roof repaired. 39,000 Q. capacity is used for packaging products for supplying authorized agencies.

Mensuration Equivalents: 1 Quintal = 0.1 Metric Ton = 220.462 Pounds

Source: Commercial Department San Salvador October 14, 1969.

GUATEMALA

No data are presented here for farm storage of grain.

Available statistics on existing storage facilities are extremely sketchy. Data available on capacity of bulk storage silos is presented in the accompanying Table 1.

No reliable information is available on the existing warehouse capacity used for storing grain. Data presented in the accompanying Table 2 on warehouse capacity for corn storage are estimates based on amount of corn produced in Guatemala and using a turn-over rate of 3.0.¹⁾

An extensive program has been undertaken to expand the storage facilities supervised by the Instituto Nacional de Comercializacion Agricola (INDECA). Recent information,²⁾ on capacities and location of the current and soon to be completed INDECA program carried out by the Ministry of Agriculture, is shown in Table 3.

GUATEMALA

TABLE 2. WAREHOUSE CAPACITY FOR CORN STORAGE

Zone	Percent of Corn Marketed ^a	Warehouse Capacity Estimates ^b
1. Central	65	11,000 ^c
2. Sur	80	50,000
3. Occidental	40	13,000
4. Occidental Media	50	4,000
5. Nor Occidental	40	13,000
6. Norte	50	12,000
7. Nor Oriental	50	6,000
8. Oriental	70	10,000
9. Sur Oriental	70	9,000
TOTAL		128,000

a) Data on the percentage of corn marketed in the various zones are not available. These percentages represent assumptions based on discussions with personnel of the Ministry of Agriculture in Guatemala.

b) These figures are rough estimates of capacity needed to store marketed grain within the region if the average turnover rate is equal to 3. Figures for zone 2 take into account grain movement to zone 1.

c) A substantial part of this capacity may in fact be located in Guatemala City.

1) Personal communication, U.S. Agricultural Attaché, March 12, 1975.

GUYANA

No data are presented for on-farm or private sector storage. Available information, in general, indicates "untenable" sanitation conditions in paddy storage, rice storage and processing properties.

Construction of paddy storage centers began in late 1970 to have a capacity of 51,800 long tons, sufficient for about 25 percent of the projected crop. Storage for 9,312 long tons of milled rice in 24 bulk bins was scheduled for Georgetown.

According to recent information, the Guyanese Government has recently completed modern facilities for paddy and milled rice. The modern silos with dryers are located in the producing areas and have a total capacity of 30,000 M.T. of paddy rice. The bulk milled rice storage facility has a capacity of 9,200 M.T. and is located near the port of Georgetown.¹⁾

A flour mill stores wheat, however, the capacity is unknown.¹⁾

¹⁾ Personal communication, U.S. Agricultural Attaché, February 24, 1975.

HAITI

Data on storage capacities and types are virtually non-existent.

Common farm storage methods include:

- (1) Portable storage bags made of plaited palm leaves, baskets or 55-gallon oil drums placed in living huts.
- (2) Thatched huts built on tall stilts.
- (3) Bundles of husk-protected ears of maize suspended by wires or ropes from tree branches.
- (4) Thatched roof granaries with walls made of clay mixed with plant material.

USAID/Haiti is presently considering funds to construct 1100 ferro cement "Thallos" of 2-ton capacity for rural storage. Because of farm size (average less than 1 hectare) and crop diversity, a 2-ton bulk storage unit does not seem practical.

Off-farm bulk storage owned by Institut de Developpement Agricole et Industriel (IDAI) includes:

<u>Location</u>	<u>No. Units</u>	<u>Type</u>	<u>Unit Capacity</u>	<u>Total Cap</u>
		Round		
Les Cayes	7	Corrugated Metal	35 M.T.	245
Miragoane	3	"	"	105
Jacmel	3	"	"	105

HONDURAS

We have no information on farm storage capacities or methods in Honduras.

Data presented here indicate capacities for storage controlled by Banco Nacional de Fomento and does not include capacities for commercial or cooperative organizations.

MEXICO

It is estimated that approximately 80 percent of the off-farm grain storage capacity in Mexico is owned and controlled by the government agency, Almacenes Nacionales de Deposito, S. A. (ANDSA). The remaining 20 percent of the country's commercial scale storage capacity is privately owned.

Much grain is obviously stored on-farm in small quantities, however, no data are available on total quantities.

Total capacity of ANDSA is reported as 3.7 million metric tons. Location and capacities of ANDSA storage facilities are indicated in the accompanying table. There are 646 warehouses in the ANDSA system. Total commercial capacity is estimated at 4.6 million metric tons for Mexico but there is no estimate of the number of private facilities.¹⁾

NICARAGUA

No data is presented here on farm storage types or capacity.

Data available on government and commercial grain storage is incomplete and should be considered as estimates.

The National Emergency Committee in July 1973 indicated the storage capacity for basic grains at that time was:

Government Storage	119,000 Metric Tons
Private Sector Storage	<u>86,363</u>
TOTAL	205,363 Metric Tons

More recent information indicates government (INCEI) storage as 152,500 metric tons on December 31, 1974 with an additional 19,500 metric tons possibly under construction.¹⁾ INCEI's storage types and locations are indicated as follows:

	<u>Assumed Bulk Storage</u>	<u>Horizontal Warehouses</u>	<u>Total</u>
Terminal No. 1 Managua	7,000 M.T.	(1) 7,500 M.T.	14,500
Terminal No. 2 Chinandega	12,000	--	17,000
Terminal No. 3 San Isidro	12,000	--	17,000
Location Unknown			
100 units at 24,000 q.q.	120,000	--	120,000
2 Inflatable Warehouses	--	(2) 3,500	3,500
40 Horizontal Warehouses	--	(40) 10,000	10,000
TOTAL INCEI STORAGE	<u>151,000</u>	<u>21,000</u>	<u>182,000</u>

¹⁾ Personal Communication, U.S. Agricultural Attaché, Feb. 20, 1975.

PANAMA

Panama's total grain storage capacity in 1970 was 1,876,700 quintals. This includes 321,400 quintals of Government capacity and 1,555,300 quintals of private industry capacity. Of this amount, 85,000 quintals of Government capacity and 130,000 quintals of private industry capacity are silos for storage in bulk. By location in the marketing system, the breakdown of the total storage capacity is as follows:

- Country points, 268,800 quintals
- Terminal points, 1,475,400 quintals
- Distribution warehouses, 132,500 quintals

In 1969-70 the average annual turnover of the country and terminal capacity was 1.49. The average turnover of the distribution capacity was 10.68. It is believed that under conditions in Panama, the average annual turnover capacity can be raised to 2.0 for the country and terminal capacity and 12.0 for the distribution warehouse capacity.

On this basis and the projected marketing volumes, the additional grain storage facilities to be needed by 1979-80 include the following:

<u>Type of Facility</u>	<u>Replacement</u>		<u>Additional</u>	
	<u>Number</u>	<u>Capacity (qq)</u>	<u>Number</u>	<u>Capacity (qq)</u>
Country storage (bags)	18	48,200	34	261,000
Country storage (silo)	-	-	4	90,000
Terminal storage (bags)	10	284,000	5	64,000
Terminal storage (silo)	-	-	10	576,000
Distribution warehouses (bags)	-	-	11	127,000
	<u>28</u>	<u>332,200</u>	<u>64</u>	<u>1,118,000</u>

Additional storage facilities will be needed in all provinces, but the needs will be concentrated in Chiriqui and Cocle where production is growing rapidly, and in Panama where demand is growing most rapidly. Some of the needed expansion should be Government-owned facilities, but the greatest improvement and expansion is needed in the private sector of Panama's grain marketing system.

Reference: Phillips, R. (1973), "Needs and Opportunities for Improved Grain Marketing in Panama, Executive Digest." Food Grain Drying, Storage, Handling and Transportation - Report No. 36, Food and Feed Grain Institute, Kansas State University.

Mensuration Equivalent: 1 Quintal = 0.1 Metric Ton = 220.462 Pounds

PERU

No data is presented here on farm storage types or capacities.

Rice and wheat storage shown in the tables on the following pages, with the exception of the port facilities at Callao and Matarani, would be classified as private storage.

In addition to the rice and wheat storage, several agencies have grain and/or food storage facilities.

1. There is an unknown capacity for storage at one malting plant and two corn processing plants near Lima.

2. Welfare agencies such as CARITAS and OFASA are said to have a warehouse capacity of up to 12,000 M.T.

3. ONAA, the government food distribution agency, is completing a new storage and warehousing facility of approximately 15,000 M.T.

Plans for expanding storage capacity include:

1. A government system for storing rice (capacity unknown).

2. Additional storage of 5,000 M.T. at Matarani Port and 35,000 M.T. at Callao Port. (The October 1974 earthquake has delayed construction of new silos and severely damaged existing ones.)

3. EPSA has plans for building an additional 200,000 M.T. for rice storage.

/1 Concrete areas for piling grain, sometimes under shelter.

TRINIDAD

There is a total capacity for storage of bulk grain in Trinidad of approximately 27,670 M.T. which is utilized as follows:

FLOUR MILL

Wheat 14,970 M.T.

GRAIN TERMINALS

Corn 10,160 M.T.

Soybeans 2,540 M.T.

Facilities for bulk unloading are provided at the terminals for the grains which are imported.¹⁾

¹⁾ Personal Communication, U.S. Agricultural Attaché, February 24, 1975.

URUGUAY

Data included in the accompanying table indicates location and capacities of grain storage under the Ministry of Agriculture, Technical Working Group on the National Silos Plan.

VENEZUELA

Data reported in the following tables refers to all types of storage facilities (silos, warehouses and flat storage). The two terminal facilities indicated are used primarily for loading and unloading shipments arriving at ports and might not be considered storage facilities in the strict sense.

In 1974 it was reported that Venezuela had just enough storage capacity to cover all crop production and imports. Wheat, sorghum, soybeans and soybean meal are imported on a month-to-month basis.

ADAGRO, which owns most of all government storage in Venezuela, increased its storage capacity from 447,000 M.T. in 1973 to 493,000 M.T. in 1974. To cover the forecasted increase in crop production in 1975/76, ADAGRO officials expect to increase their storage capacity to 1,041,000 M.T. ADAGRO anticipates a need for 1.81 million M.T. total storage capacity by the end of 1975 and 2.5 million M.T. by the end of 1976 to accommodate expected increases in crop production.¹⁾

No data for farm storage capacities or methods are included here.

¹⁾ Personal communications, U. S. Agricultural Attaché, March 11 and 17, 1975.

STORAGE CAPACITY IN VENEZUELA

Footnotes:

- 1/ ADAGRO is government entity responsible for bulk of all government storage facilities.
- 2/ Estimates of private storage facilities based on ADAGRO data and adjusted as indicated to agree with estimates from private trade sources.
- 3/ Equal to difference between total rice, corn, wheat, and animal feed ingredient storage minus total storage capacity identified by type of ownership.
- 4/ Based on Anuario Estadístico Agropecuario, 1973, Ministerio de Agricultura y Cría.
- 5/ Based on estimates from private trade sources.
- 6/ Difference between total storage capacity identified by type of ownership minus total rice, corn, wheat, and animal feed storage.
- 7/ Apure's crops stored in Guarico.
- 8/ ADAGRO estimate of 12,132 m.t. increased to 50,000 m.t. to agree with private trades estimate of total wheat and feed ingredient storage capacity under private ownership in State of Anzuategui.
- 9/ ADAGRO estimate of 18,735 increased to 60,500 m.t., private trade's estimate of total wheat and feed-grain capacity under private ownership in State of Zulia.
- 10/ Includes 12,000 m.t. of government terminal storage in La Guaira.

AFGHANISTAN

No data are presented for farm or privately operated storage facilities. Small producers may store grain in pits underground. Larger producers' and merchants' storage usually consists of a room in the home or place of business where bags of grain are stored. Except for grain storage visible in bazaars, very little is known about producer, merchant or private operator storage. Privately owned facilities designed for grain storage are practically non-existent.

Storage facilities maintained by the Food Procurement Department (the government agency responsible for grain storage) are shown in the accompanying table.

ALGERIA

Algeria is provided with a network of silos and warehouses which are spread throughout the country. The silos and warehouses have been developed under two national plans for storage, one started in 1939 and another conceived in 1961. All storage facilities are Government property or controlled by the "Office Algèrien Interprofessionnel des Céréales" (OAIC). OAIC has the responsibility of maintaining a readily available supply of grain, either through local purchases or imports, for Algerian consumption.

Capacities of the Algerian grain storage network for 1968 are shown in the accompanying table. It should be pointed out that elevators can be used to 80-85 percent of stated capacity and capacities of "specially fitted warehouses" should be considered 60-65 percent of that stated. The "not specially fitted" and rented warehouses are, on the whole, small and not suitable for prolonged storage.

Indications are that a storage deficit exists in the Constantine Region and that additional capacity is needed at the Port of Algiers.¹⁾

No data on farm storage are included.

TOTALS	530	391	161	163	1,245

SOURCE: FAO, Commodities and Trade Division, 1968.

BANGLADESH

On the average, less than one sixth of the total grain in storage in Bangladesh is held on Government account. Approximately 50 percent of all grain moving through market channels is imported and handled by the Food Department.

In the aggregate, farm and dealer stocks account for about 84 percent of the total grain stored. Rice is stored in the rough (or paddy) rice form until hulled for consumption.¹⁾

Private storage capacity for the most part is leased by the Food Department.¹⁾

Fairly extensive data was published by Weitz-Hettelsater on location and types of storage controlled by the Government in 1964. Local Supply Depot (LSD) godowns with capacity of 408,365 tons were controlled by the Directorate of Procurement, Distribution and Rationing, Food Department. Central Supply Depot (CSD) godowns with capacity of 254,169 tons were controlled by the Directorate of Movement and Storage, Food Department. (See Tables 1 and 2.)

More recent information²⁾ indicates that total storage capacity existing November 1973 was as follows:

TYPE OF STORAGE	CAPACITY
<u>Silos</u>	225,000 M.T.
Chittagong 100,000 M.T.	
Narayangari 75,000 M.T.	
Ashuganj 50,000 M.T.	
Central Supply Depot (CSD)	360,000 M.T.
Local Supply Depot (LSD)	473,000 M.T.
TOTAL	<u>1,058,000 M.T.</u>

EGYPT

A report prepared by Weitz-Hettelsater Engineers in 1961¹⁾ recommended a total of 743,000 M.T. silo storage and 210,000 M.T. of flour storage for Egypt. Silo storage recommended at Alexandria and Cairo was 80,000 M.T. and 120,000 M.T., respectively.

A recent study indicated that the only major permanent storage facilities now existing consist of a 48,000 M.T. complex in Alexandria at the port unloading site and a 58,000 M.T. complex in Cairo located on the Nile River's west bank. Both facilities consist of permanent concrete bins and were constructed in 1962.²⁾

Sacked grain is stored in open areas known as "shounas." Shouna's are the primary means of storing bagged grains in Egypt. Sacks of grain are stacked 9 to 10 sacks high on 4-inch square timbers spaced 18 inches apart on bare earth.

Enclosed warehouses available for storage are few and appear to be primarily used for sacked flour and a minor amount of sacked brown beans.²⁾

1) Grain Storage and Distribution System for Agricultural Credit and Cooperative Bank -- Southern Region, United Arab Republic" Weitz-Hettelsater Engineers, Inc. August 1961.

2) Jack, D. S. (1975) Evaluation and Cost Estimates for Grain Unloading, Storage and Distribution Facilities in Egypt. Grain Storage, Processing and Marketing Report No. 50. Food and Feed Grain Institute, Kansas State University, Manhattan, Kansas May 1975.

INDIA

No data is presented here on capacities or quantities of grain on farms.

Farm storage methods vary by region and type of grain. Storage of paddy rice by farmers, for food or seed, is very often in bulk, in locally constructed containers which may be made from a range of materials. Wheat stored on farms may be stored in bags or in bulk. Bulk quantities may be retained in a corner of a room by woven wall or it may be stored in mud or wooden bins within dwellings. Oil drums have been used for this purpose also. In dry regions wheat is stored in underground pits.

After being sold in the market place nearly all grain is handled in bags on storage until processed for consumption.

Traders and millers in primary and terminal markets store grain stocks in private warehouses known as "godowns." Godowns are usually constructed of brick and mud or brick and mortar. No information exists on the extent of such warehouse space in markets. Public or government operated warehouses storage capacity is said to account for only about 5 percent of the total food grain production. In addition to the warehouse storage space in the accompanying table at least two 10,000 M.T. capacity metal silos have been constructed with U.S. assistance.

IRAN

Information available for this publication is conflicting with respect to storage capacity estimates for Iran. It should be pointed out that this is not uncommon when data is available from various sources.

The most complete and recent information on existing storage facilities is shown in Table 1.

In other undocumented information,¹⁾ estimated storage available as of April 1974 included:

	<u>Metric Tons</u>
Farm	1,440,000
Milling Industry	1,500,000
Cereals Organization	
Warehouses	334,000
Silos	716,000
	<hr/>
TOTAL	3,990,000

Other undocumented information,¹⁾ indicated that in 1968 all permanent storage facilities were government owned and operated by the "Cereals Administration" primarily for wheat bought and sold by the Administration. An estimate of 176,000 M.T. of cement silo capacity existed in cities and that an additional 79,000 M.T. of cement silo capacity would be completed in producing areas in 1968.¹⁾

¹⁾ FAO, Commodities and Trade Division.

JORDAN

Data reported as open storage at mills would normally not be considered suitable for safe storage of grain. It consists of asphalt or concrete paved surfaces adjacent to flour mills.¹⁾

¹⁾ Personal Communication, U. S. Agricultural Attache, Beirut, February 5, 1975.

Source: Above data on grain storage facilities has been obtained from the Ministry of Supply, except for data under the heading "Private" which represents USAID/Amman's best estimate. No reliable statistics on private grain storage facilities are available.

NOTE: The Government of Jordan is constructing additional storage facilities for 20,000 tons of bagged grain at Ruseifeh and Amman. Land was bought at Ma'an and Irbid to build government grain storage facilities for 5,000 M.T. and 20,000 M.T. respectively. Plans have also been made to construct small grain storage units in various districts with an average capacity of 40,000 - 50,000 tons. The Jordanian Government is contemplating the construction of a bulk grain handling and storing facility at Aqaba Port for approximately 30,000 tons. The Jordanian Government has requested USAID to finance the services of an engineering firm to: (1) review available studies, reports and other materials on grain storage in Jordan, (2) recommend the size and type of grain storage facility needed at Aqaba, and (3) design the facility together with the associated grain handling equipment and prepare specifications and tender documents needed to invite bids for construction.

LEBANON

No data are included here for farm or private (flour mills, feed mills, etc.) grain storage facilities.

The Lebanese Cereals and Sugarbeet Office operates the following grain storage facilities:

<u>Location</u>	<u>Storage Capacity (M.T.)</u>		<u>Remarks</u>
	<u>Flat Storage</u>	<u>Bulk Storage</u>	
Beirut	--	105,000	Port Silo
Sidon	1,000	--	Rented
Tel Amara	15,000	--	Additional 6,000 M.T. under const.
Tripoli	--	5,000	
TOTAL	16,000	110,000	

SOURCE: Personal Communication, U. S. Agricultural Attaché, Beirut.
February 5, 1975.

MOROCCO

Data included here appear to be the most reliable figures available although there were discrepancies between data from various sources.

Storage of grain on farms is for the most part accomplished in underground earthen pits. The pits hold as much as 110 quintals and approach hermetic or "airtight" storage. Deterioration apparently is not severe in this type of storage. No estimate of farm storage capacity is available.¹⁾

In addition to data presented in the accompanying tables, more recent information indicates that silo storage capacity at Casablanca has been increased to 70,000 M.T. and at Safi to 24,000 M.T. The Moroccan Cereals Office has also indicated plans to build a 40,000 M.T. storage facility at Tangier in the "free port" area to serve international grain traders and smaller ports along the North and West African coasts.²⁾

Footnotes continued

² SCAM data (31 Mar. 1969) Combine Taza and Fes capacities and show 5,000 qx. more bulk and 5,000 qx. less warehouse capacity than shown above.

³ Figures presumably include storage in cities of Souk El Arba, Sidi Kacem, Ksiri, Sidi Slimane and Kenitra in Kenitra Province.

⁴ Elevators used primarily for import-export of grain. Elevators at Kenitra and Casablanca operated by Ministry of Commerce; Elevator at Safi operated by OCIC.

⁵ Figures presumably include storage in cities of Settat, Benahmed, Berrechid and Casablanca. However, SCAM data of 31 Mar. 1969 indicates 221,000 M.T. less silo storage and 125,000 M.T. less warehouse capacity than OCIC data of 1967.

1 Quintal = 0.1 Metric Ton = 220.462 Pounds

NEPAL

Storage practices at the farm and village level are traditionally the same throughout the country and have been used for many years without modification. The specific type of storage depends on the availability of local building materials. Storage at this level ranges from piling grain on the ground uncovered, hanging from rafters inside dwellings; storage in a variety of small containers to bins made of bamboo, mud and/or straw to wood. Recently a reinforced concrete farm bin of 4-5 ton capacity has been developed and is being used in some areas.

At the processor, cooperative or trader level, grain is stored in bags in buildings constructed of a variety of materials. Cooperative warehouses range in capacity from 50 to 500 metric tons capacity. Rice mill storage in some cases is 750 to 1,500 metric tons.

Government Food Corporation warehouses range in size from 500 to 4,000 metric tons in capacity and is used principally for milled rice.

SYRIA

In late 1971, the Syrian Arab Republic started implementation of a Grain Silos Project which consists of silos for grain storage, certified seed plants, farmers' seed plants and feed mills.¹⁾

The project consists of:

- (1) 15 grain silos located in the different Mohafazats (Provinces) with a total storage capacity of 350,000 tons. After modification and expansion, the storage capacity is predicted to be 810,000 tons. (See the accompanying table 1.)

An export silo currently exists at Latakia with a capacity of 40,000 tons.

- (2) Erection of 11 seed plants for cleaning and treating seeds for farmers. Three plants are planned, each with a capacity of 10,000 tons per year. Three fully automatic plants are to be located at Kamishly, Raqqa and Qalaat Al Madiq. Eight others will be located with grain silos.
- (3) Erection of two (2) feed production mills; one in Aleppo and the other in Hama. Annual production is to range between 40,000 and 70,000 tons per year for each mill.

As of early 1975, only the Aleppo silo has been completed under the new project and it should be in operation for the next crop.²⁾

In addition to the new silo and the silo at Latakia, Syria has storage facilities for large quantities of grain of the flat warehouse type for bagged grains. The Syrian General Organization for Cereals and Mills (GOCM) indicates a total of 450,000 M.T. storage capacity for bagged grains built by GOCM.³⁾

The Syrian Ministry of Agriculture and Agrarian Reform is also involved in building grain storage facilities with the assistance of FAO/WFP aid and government financing. See Table 2.⁴⁾

^{4]} Each unit is 750 M² with capacity of 2,250 M.T.

TUNISIA

Grain stored on farms is mainly for seed and food purposes, however, some small farms (3-11 hectares) hold grain for sale at weekly markets. Larger farms generally sell surplus grain shortly after harvest.

In the northern area of the country, grain is generally stored in a building close to the living quarters. These buildings are usually made of the same materials as the houses - sundried brick, stone or cement block walls, usually with cement floors and roofs of straw, sheet metal, brick or tile. Grain is usually stored in bulk in a part of the storage buildings.

In the southern area underground storage pits about 3-4 meters deep and 2-2.5 meters in diameter are used.

No data is available on total storage capacity on farms.

Tables 1, 2 and 3 show the location and capacity of grain collecting centers operated by the Cooperative Centrale de Blé (COCEBLE), Cooperative Centrale des Grandes Cultures (CCGC) and the Ministry of Agriculture, Office of Cereals, respectively. Total collection center storage capacity is 1,691,800 Qx. The 140 collection centers of the Office of Cereals are widely dispersed throughout the wheat production area providing small and large farmers with conveniently located marketing points.

Most centers' facilities are constructed of concrete or stone and are used for both sack and bulk grain; some - steel framed, metal roofed structure for sack storage; and there are a few of more modern bulk design.

There are twelve large terminal elevators in Tunisia of concrete or concrete and metal silos. Capacities and location of the terminals are shown in Table 4.

Two port elevators exist in Tunisia. An export elevator owned by the CCGC is located at Bizerte but lacks bulk unloading equipment. A new import/export elevator was completed in March 1974 by the Office of Cereals at La Goulette and has a total storage capacity of 30,000 M.T.

Large flour mills have only storage for sack grain, however, capacities are unknown.

TURKEY

No data on total farm or village level storage or on private traders or processors' capacities are included here. Farmers usually store 3-10 M.T. of bulk grain in rooms of the home. In some areas wooden structures raised off the ground with 5-10 M.T. capacity are used. Underground pits of about 10 M.T. capacity are used in certain areas also with a few pits of 100 M.T. capacity. Traders store grain in bulk in large rooms whereas processors store in metal or concrete bins or in warehouses in bulk.¹⁾

Data are presented from two sources showing capacities of grain storage facilities operated by the government-owned TOPRAK MAHSULLERI OFISI (T.M.O.) in 1969 and 1974 to be in close agreement (1969- 1,717,810 M.T.; 1974- 1,752,120 M.T.). Over half of the increase in capacity can be accounted for by a 20,000 M.T. concrete silo constructed at Haydarpasar in 1972.
