BACKGROUND PAPER #4

DEMAND PARAMETER ESTIMATES

Prepared by S.R. Johnson and Gary Stampley, respectively, Professor of Economics and Administrator, and Systems Analyst, Center for Agricultural and Rural Development, Iowa State University. The research was supported by a Cooperative Agreement between the U.S. Department of Agriculture, Office of International Cooperation and Development and the University of Missouri-Columbia (58-319R-4-073). A portion of the funding for the Cooperative Agreement was provided by USAID/Jamaica.

Background Report #4

Demand Parameter Estimates

1. Introduction

There are two primary data sources for use in estimating demand parameters for Jamaica: the Jamaican Household Expenditure Survey 1984, conducted by the Statistical Institute of Jamaica (STATIN) and available time series of disappearance data that have been assembled, primarily by the Ministry of Agriculture (Background Report #1, 1988). In this report, these two primary data sources are analyzed for information for evaluating consumption patterns of Jamaicans. The survey data can be partitioned by characteristics of the households. This permits analysis of food consumption patterns that are specialized to households exhibiting different characteristics. Among these characteristics are some that have been utilized in designing the Food Stamp Program. In short these data are of use for targeting food policies and for assessing impacts of food policy and food price changes.

The time series disappearance data are national, and thus more useful in indicating aggregate responses to changes in pricing and other policies, that effect markets for food commodities. Examples of these policies are those effecting trade, exchange rates, production incentives, and food aid.

The report includes four major sections in addition to the introduction. In Section 2, information on food consumption patterns prepared from the 1984 Jamaican Household Expenditure Survey is presented. Section 3 summarizes corresponding price and disappearance data extracted

from Background Report #1. In Section 4, demand parameters are estimated merging the time series and survey data. Section 5 includes some brief conclusions.

2. Survey Data Analysis

The Jamaican Household Expenditure Survey of 1984, conducted by STATIN includes expenditures for approximately 450 food items. Obviously, expenditures of the households on many of these items were zero during the week in which they are surveyed. As well, preparing a tabular analysis with food items at this level of disaggregation would be doubtful in usefulness. For these two reasons, aggregates of the food items from the survey were developed. Specifications for these aggregates were provided by staff of STATIN. They include, meats, eggs and dairy products, grains, oil, root crops, vegetables, and fruits. Addition to be representative of household food consumption patterns, the food groups were prepared to reflect commodities that are primarily imported or exported commodities. The food groups along with the expenditure item codes from the Jamaican Household Expenditure Survey are provided in Table 1.

In developing the analysis, selected features of households in the 1984 Jamaican Household Expenditure Survey were included. These were: region, stratum, parish, expenditure group, aggregate expenditure group, family size, age of household head, sex of household head, occupation of household head, and employment status of household head. Four calculations are provided in the tabular analysis using these characteristics and the food groups. These calculations include mean

availability per week per capita, mean availability per week per adult equivalent, sample size in the corresponding partition, and the sample size in the partition as a proportion of the total sample.

Of the calculations presented, the two availability figures require additional comment. First, the mean availabilities per week are for purchased, home production, and foods received as gifts or payments. They represent availability, and it is important to recognize that availability is not equal to disappearance. The survey data did not include information to permit correction for beginning and ending inventories of the households during the week of the interview.

The mean adult equivalent availabilities were developed from the information on household composition. That is, the adult equivalent is interpreted the same as the per capita figure, except that the count of household members is weighted. The weights employed were 1 for male adults (15 and older), .8 for female adults (15 and older), and .6 for males and females (under the age of 15). These weights are included in an attempt to reflect the "requirements" of the different household members. They are similar to weights used in usual FAO/UN evaluations of food consumption patterns.

The tables containing these calculations of mean availability by sample partition are included in the appendices (Tables A-1a to A-10x). The appendices are organized by food group. Ordering of the food groups in the appendix tables is consistent with the ordering of the food group definitions in Table 1. For the discussion to follow, summaries have been prepared from the appendix tables. This discussion is organized by food group. Data have been extracted from the appendix tables to allow

comparisons of availabilities by region--Kingston, Other Towns, Rural--and income--expenditure groups, \$0-\$24,000 and \$24,000 and above. The objective is to highlight the information that is contained in the appendix tables.

Meats

The per capita availability level data for meat are summarized by region in Table 2. Values are mean availabilities per week from purchased, home production, and food received as gift or payment. From Table 2, it is apparent that poultry consumption is the highest of the five meats, followed by beef, fish, pork, and mutton. Pork is consumed more by households in Other Towns and in Rural areas. Fish is consumed in larger quantities by households in Other Towns and in Kingston than in Rural areas. Mean average per capita availability for poultry is more than twice as large as the mean figure for any of the other meats. Total per capita meat availability in Kingston is 2.3 pounds per week on average. For Rural households, this total is 2.10, perhaps related to relative price and the lower incomes or total expenditures of Rural households.

Similar data for the five meat groups are provided in Table 3. In Table 3, the households are partitioned by expenditure group, \$0-\$24,000 and \$24,000 and above. As can be observed from Table 3, the higher income households consume more meat. Poultry meat remains the member of the group with the highest mean availability per week. Consumption from the beef group nearly doubles in the higher income households. Mean availability per week in the high income households for all meats is 3.13

pounds per capita per week, almost one pound per capita higher than for the low income or low total expenditure households. Recall from other background reports that the income data in the Jamaican household expenditure survey of 1984 were not well reported. For this reason, total expenditures is used here and in subsequent tables as a proxy for household income.

Eggs/Dairy Products

Mean availabilities per week from purchase, home production, and gifts of eggs and dairy products are provided in Table 4. Observe from Table 4, that the highest consumption of dairy products is condensed sweetened milk. Consumption of other dairy products is quite low. Butter in particular occupies an almost insignificant place in the food consumption patterns of the Jamaican households. Comparing Rural, Other Towns, and Kingston, major differences appear to be for milk, condensed and sweetened milk, and eggs. Households in Kingston consumed nearly twice as many pounds per capita per week on average of eggs as Rural households. Rural households consumed more milk and less condensed sweetened milk than the Kingston households and the households in Other Towns.

Evaluating the mean availabilities per week relative to the two expenditure groups provide some interesting observations. Milk consumption is higher in the higher expenditure group on average (but the difference is not as large as the difference between the Kingston and the Rural households. Both high and low expenditure households consumed relatively large average amounts per week of condensed sweetened milk. Egg consumption is approximately twice as high in the higher total

expenditure group households as in the lower expenditure group households. Butter consumption remains low, but increases in the higher expenditure group. Per capita powdered milk consumption is low in both high and low expenditure group households and across the three regions. Interestingly, this is a commodity that is included in those eligible for purchase with food stamps.

Grains

Grains are major staple foods in Jamaica. Observe that rice consumption is higher in Kingston and in Other Towns than in Rural areas. Cornmeal consumption is relatively constant across the three regions. Wheat flour is consumed more highly in Other Towns and Rural areas than in Kingston. Total grains consumption, in mean availabilities per week from foods purchased, from home production, and received as gift or payment is 2.61 pounds per capita per week in Kingston. There is lower grains consumption in Rural areas than in Other Towns and in Kingston, perhaps due to the use of root crops as substitutes for these staples in the diets.

Comparing the households by income group, the major difference is for rice. Mean availability per week from purchased foods, home production, and gifts or payments for rice is higher for the households in the higher expenditure group than in the low expenditure group. This difference is more-or-less offset by higher average per capita consumption for wheat flour in the lower income group. Average per capita cornmeal consumption per week is nearly the same for the households in the high and low expenditure groups. Comparing the differences in total expenditures for

the groups to the differences in consumption, the income elasticities for wheat flour used for baking and rice, would be positive. Negative income elasticities would be observed for wheat flour and the income elasticity for cornmeal would be approximately zero. Care must be followed in making these elasticity calculations, given the fact that there is a broad range between the midpoints of the two income groups. However, these differences in consumption do at least indicate the size of the income elasticity, and interesting that wheat flour from the counter is an inferior good.

Oil

Mean availability data for three oil food groups are provided in Table 8. The three oil groups are coconut, vegetable, and other cooking oils. Coconut oil consumption is higher in other towns and in rural areas. Vegetable and other oil consumption is higher in Kingston than in the other three areas. However, these differences are minor and would likely be insignificant if evaluated statistically. Generally, oil consumption is relatively low, about .28 pounds per capita per week in Kingston for example.

Table 9 shows that oil consumption increases with income. The increase is larger for other cooking oils than for coconut or vegetable oil. This may be a function of both availability and price, since the households in the Other Towns and in Rural areas have lower incomes but also may be in a position to purchase coconut oil at lower prices. Total oil consumption difference between the households in the high expenditure group and the low expenditure group is less than one-tenth of one pound per week on average.

Root Crops

The two root crop groups are potatoes and yams. Average availability data provided for these two root crops are in Table 10. Observe the higher consumption of root crops in the Rural areas compared to Kingston. Per capita consumption of yams in Rural areas is more than double that in Kingston, on average. Potato consumption is higher also in Rural areas, but not by as large a factor.

Yams and potatoes consumption by expenditure group is shown in Table 11. The differentials between the income groups are not as large as the differentials between the regions. Also, yams consumption is higher in the low income group than in the high income group. This is in part due to the fact that the low income groups are in rural areas where yams may have a lower price due to storage, availability, and other factors. But, low income and high income households are consuming substantial quantities of these two root crops on average.

Vegetables

Tomatoes and bananas are obviously vegetables. Instead, they are fresh fruits, but of a type that yield different dietary components than commodities labeled fruits. From Table 12, observe that average availabilities per capita per week of green bananas are high in all regions. Average consumption is higher in Rural areas than in Kingston. Average availability for tomatoes per capita is higher in Kingston than in Rural areas.

These data are summarized by the two expenditure groups in Table 13. From Table 13, note that green bananas consumption is higher in the low

income or expenditure group households than in the high expenditure group households. The reverse is true for tomatoes. Fresh green beans are consumed on average about the same in both the high income households and in the lower income or total expenditure households.

Fruits

Average availabilities per capita per week for fruits, oranges and grapefruit, are provided in Tables 14 and 15. Oranges are consumed more in Kingston and by higher income groups. The same is true for grapefruit. Higher income households consume nearly two pounds of oranges and grapefruit per week.

3. Summary

The data summarized in the previous section are indicative of much more detailed information provided in the appendix tables. By using the sample proportions in the appendix tables and the inflation factors provided by STATIN, estimates of population disappearance for these food items or alternatively food groups can be obtained from Jamaica. These data can be compared to the disappearance data. Clearly, corrections for spoilage, disappearance in nonconsumptive uses, and other factors will make the disappearance data larger than the data estimated on the basis of the quantities from the household expenditure surveys. However, the relative magnitudes will be useful in identifying trends and patterns and most importantly, in showing the relative consumption patterns among households with different features. It is the distributional aspects of policies to influence price, income, and other factors that can be best evaluated with the expenditure survey data.

In a later version of this report, two additional sections will be included. The first section will be the time series disappearance data. An attempt will be made to make these disappearance data consistent with the groupings that have been developed for the summarization of the data from the 1984 Jamaican Household Expenditure Survey. Direct comparisons can then be made between the disappearance data and the "inflated" values for the household expenditure survey data as a basis for evaluating the impacts of trends and consumption patterns, changes in demographics, and other aspects of the population.

The second major section to be included will be one in which demand parameters are estimated. Currently, on the basis of the income group/availability data on the tables provided in the text and in the appendices, crude estimates of income elasticities can be developed. It is for example, assuming that prices are constant across regions, possible to infer the sign of the income elasticity and whether goods are inferior or superior from the differences in consumption compared to the differences in income or total expenditure.

Demand systems have been estimated from the 1984 household expenditure data. Specifically, an Almost Ideal Demand System has been estimated for food groups relatively highly aggregated. However, these estimates can be useful in the time series data. Among the difficult parameters to estimate from either the time series disappearance and price data or the expenditure data are the cross-price elasticities. These cross-price effects are especially important in policies designed to intervene in food consumption patterns, markets, and in determination of income. Observing the results available from the summaries in the

previous section, it is interesting to note that of the three items which food stamp payments can be made, skim milk powder, cornmeal, and wheat flour, wheat flour is an inferior good. Consumption of skim milk powder is quite low, suggesting preferences for other sources of dairy products. Alternatively, cornmeal appears to be a staple food for both high and low income groups.
