October 1998

This report highlights the findings of the 1997 Indonesia Demographic and Health Survey (IDHS) undertaken by the Central Bureau of Statistics in collaboration with the State Ministry of Population/National Family Planning Coordinating Board (NFPCB) and the Ministry of Health (MOH). The DHS Project of Macro International Inc. provided technical assistance and some funding. All of the local costs for the survey were provided by the Government of Indonesia. USAID/Jakarta provided additional funding for technical assistance through Macro International Inc.

The 1997 IDHS is part of the worldwide Demographic and Health Surveys (DHS) program, which is designed to collect, analyze, and disseminate demographic data on fertility, family planning, maternal and child health. Additional information on the 1997 IDHS may be obtained from the Central Bureau of Statistics, Jl. Dr. Sutomo 8, Jakarta 10710, Indonesia (Telephone 345-6285; Fax 384-1545), or the State Ministry of Population/National Family Planning Coordinating Board, Jl. Permata 1, Halim Perdanakusumah, Jakarta 13650, Indonesia (Telephone 800-9029; Fax 800-9125), or the Institute for Health Research and Development, Ministry of Health, Jl. Percetakan Negara 29, Jakarta 10560, Indonesia (Telephone/Fax 424-4226). Additional information about the DHS program may be obtained by writing to: Macro International Inc., 11785 Beltsville Drive, Calverton, Maryland 20705-3119, USA (Telephone 301-572-0200; Fax 301-572-0999).

 CHAPTER 1 INTRODUCTION	 1
1.1 Geography, History, and Economy	1
1.2 Population	2
1.3 Population and Family Planning Policies and Programs	4
1.4 Health Priorities and Programs	4
1.5 Objectives of the Survey	5
1.6 Organization of the Survey	6
 CHAPTER 2 HOUSEHOLD CHARACTERISTICS AND WOMEN'S SITUATION	 9
2.1 Household Population by Age and Sex	9
2.2 Population by Age from Other Sources	9
2.3 Household Composition	11
2.4 Level of Education of the Household Population	12
2.5 School Enrollment	15
2.6 Housing Characteristics	16
2.7 Household Durable Goods	20
2.8 Respondents' Background Characteristics	20
2.9 Respondents' Level of Education by Background Characteristics	21
2.10 Access to Mass Media	22
2.11 Employment	22
2.12 Occupation	23
2.13 Decisions of Use of Earnings	25
2.14 Child Care While Working	27
 CHAPTER 3 FERTILITY	 35
3.1 Fertility Levels and Trends	35
3.2 Fertility Differentials	38
3.3 Children Ever Born and Living	40
3.4 Birth Intervals	41
3.5 Age at First Birth	41
3.6 Adolescent Fertility	44

	Page
CHAPTER 4 KNOWLEDGE AND EVER USE OF FAMILY PLANNING	49
4.1 Knowledge of Family Planning Methods and Sources	49
4.2 Knowledge of Blue Circle	53
4.3 Knowledge of Golden Circle	55
4.4 Dissemination of Family Planning Information	56
4.5 Source of Family Planning Information	59
4.6 Discussion on Family Planning With Husband	64
4.7 Ever Use of Family Planning Methods	65
CHAPTER 5 CURRENT USE OF FAMILY PLANNING	69
5.1 Current Use of Family Planning	69
5.2 Trends in Contraceptive Use	71
5.3 Contraceptive Use Among Women Over 30 and Among Those with Three or More Children	74
5.4 Reasons for Choice of Contraceptive Method	75
5.5 Quality of Use of the Pill, Injection and Condoms	77
5.6 Problems with Current Method	77
5.7 Cost and Accessibility of Methods	78
5.8 Source of Method	80
5.9 Timing of Sterilization	83
5.10 Knowledge of the Fertile Period	85
5.11 Knowledge of the Effects of Breastfeeding on Pregnancy	87
CHAPTER 6 FERTILITY PREFERENCES	93
6.1 Desire for Additional Children	93
6.2 Ideal and Actual Number of Children	96
6.3 Need For Family Planning Services	98
6.4 Unplanned and Unwanted Fertility	103
CHAPTER 7 NONUSE AND INTENTION TO USE FAMILY PLANNING	107
7.1 Discontinuation Rates	107
7.2 Reasons for Discontinuation of Contraceptive Use	108
7.3 Intention to Use Contraception in the Future	108
7.4 Reasons for Nonuse	109
7.5 Preferred Method	111

	Page
CHAPTER 8 OTHER PROXIMATE DETERMINANTS OF FERTILITY	113
8.1 Current Marital Status	113
8.2 Age at First Marriage	115
8.3 Age at First Sexual Intercourse	116
8.4 Recent Sexual Activity	117
8.5 Postpartum Amenorrhea, Abstinence and Insusceptibility	120
8.6 Termination of Exposure	125
CHAPTER 9 INFANT AND CHILD MORTALITY	129
9.1 Background	129
9.2 Assessment of Data Quality	129
9.3 Levels and Trends in Infant and Child Mortality	131
9.4 Mortality Differentials	133
9.5 High-Risk Fertility Behavior	136
CHAPTER 10 MATERNAL HEALTH	139
10.1 Antenatal Care	139
10.2 Place of Antenatal Care, Number of Antenatal Care Visits, and Stage of Pregnancy	140
10.3 Tetanus Toxoid Vaccination	144
10.4 Iron Pills	145
10.5 Place of Delivery	147
10.6 Assistance during Delivery	151
10.7 Delivery Characteristics	154
10.8 Complications of Delivery	156
CHAPTER 11 IMMUNIZATION OF CHILDREN	159
11.1 Health Cards	159
11.2 Immunization Coverage	160
11.3 Immunizations by Background Characteristics	161
11.4 Immunizations by First Year of Life	164
11.5 Distribution of Vitamin A for Children	164
CHAPTER 12 CHILDHOOD DISEASES	169
12.1 Acute Respiratory Infection	169
12.2 Prevalence and Treatment of Fever	171
12.3 Diarrheal Disease	174

	Page
CHAPTER 13 INFANT FEEDING	193
13.1 Prevalence of Breastfeeding and Supplementation	193
13.2 Duration of Breastfeeding	197
CHAPTER 14 KNOWLEDGE OF AIDS	201
14.1 Source of Information about AIDS	201
14.2 Knowledge of Ways to Prevent AIDS	201
14.3 Women's Perceptions of the Risk of Getting AIDS	203
14.4 AIDS Prevention Behavior	204
14.5 Knowledge and Use of Condoms	205

PREFACE

The 1997 Indonesia Demographic and Health Survey (IDHS) is the fourth survey on demography and health in Indonesia and was conducted as part of the worldwide Demographic and Health Surveys (DHS) project. The first survey was the 1987 National Indonesia Contraceptive Prevalence Survey (NICPS), the second and third surveys were the 1991 IDHS and 1994 IDHS. The 1997 IDHS was designed as a collaborative effort of four institutions, i.e., the Central Bureau of Statistics (CBS), the State Ministry of Population/National Family Planning Coordinating Board (NFPCB), the Ministry of Health, and Macro International Inc. The Government of Indonesia/NFPCB provided all of the local costs through the Demographic and Health Surveys (DHS) program, a USAID-funded project carried out in many developing countries. The CBS was responsible for conducting the survey, including survey design, fieldwork, and data processing.

The 1997 IDHS fieldwork was carried out from September to December 1997 in selected enumeration areas in all of the 27 provinces in Indonesia. The sample is a replication of the 1994 IDHS sample, which is a subsample of the 1994 National Socio-Economic Survey, and was designed to produce reliable estimates of major variables for each province and for urban and rural areas of the three family planning program development areas (Java-Bali, Outer Java-Bali I, and Outer Java-Bali II).

The main objective of the 1997 IDHS is to provide policymakers and program managers in population and health with detailed information on fertility and family planning; infant, child and maternal mortality, and maternal and child health. The content of the 1997 IDHS was expanded from prior surveys to include a module on family welfare which will not be covered in this report. The survey no longer investigated the availability of family planning and health services as in the 1994 IDHS.

This report supplements the preliminary report released earlier. The success of this very important undertaking would not have been realized without the relentless effort and dedication of all parties concerned. To those who actively contributed to this project, I would like to extend my gratitude and appreciation, especially to USAID and the DHS program of Macro International Inc.

Sugito, MA
Director General

PREFACE

The Indonesia Demographic and Health Survey (IDHS), which is part of the Demographic and Health Surveys (DHS) Project, is one of prominent national surveys in the field of population, family planning, and health. The survey is not only important nationally for planning and evaluating population, family planning, and health developments, but is also important internationally since IDHS has been designed so uniquely that it can be compared with similar surveys in other developing countries.

The 1997 IDHS is the most recent of four similar surveys done in Indonesia. The first survey was conducted a decade ago (1987), the second in 1991, and the third in 1994. As is true for the past surveys, the 1997 IDHS, which covers around 29,000 respondents of ever-married women age 15-49, is meant to collect such important data and information as fertility levels, family planning, maternal and child health services, availability and accessibility of family planning and health services, as well as information on knowledge and attitude toward HIV/AIDS. These data and information are very beneficial and needed by various government institutions such as the Department of Health, the State Ministry of Population/NFPCB, as well as other government and private institutions that are associated with or are interested in population, family planning, and health issues.

The Indonesia Demographic and Health Surveys have long been known to have good "reputation" since they collect so much population, family planning, and health information of excellent quality. Given their variability and representativeness, the data should be and need to be used optimally. In addition to the benefits gained by the government/decision makers in developing policies and programs in the field of population, family planning, and health, this large data set that contains rich information should also be used by professionals and academicians in their effort to study social theories or phenomena. These efforts should be made much easier due to the current rapid development of advanced techniques in quantitative analysis and the advanced technology of personal computer.

Finally, I would like to express my deepest gratitude to the Central Board of Statistics (CBS), Macro International Inc in Maryland (USA), USAID, the 1997 IDHS Steering and Technical Committees, and the Office of Training and Development Programs of NFPCB for their contribution in conducting the 1997 IDHS. The high quality of the 1997 IDHS final report is indicative of the professional manner in which this project was designed and implemented.

State Minister of Population/
Chairman, National Family Planning
Coordinating Board,

Prof. dr. Ida Bagus Oka

PREFACE

Health Law No. 23/1992, which provides a legal basis for health sector activities, stipulates that the goal of health development is to increase the awareness, willingness, and ability of everyone to live a healthy life. The strategy adopted to improve the health and nutritional status of the population, following the National Guidelines on State Policy 1993, is two pronged: to improve the quality of health services, which must become affordable to all layers of the population; and to promote a healthy lifestyle supported by adequate housing and environmental sanitation. The Indonesian Ministry of Health's priorities are to improve the quality distribution of health services, with particular attention to the poor. Strengthening the preventive and promotive activities aimed at reducing maternal, infant, and child mortality and morbidity, reducing fertility, and improving nutritional status and improve the quality of health services and associated referral systems are among the major objectives of the Sixth Five-Year Development Plan (REPELITA VI, 1994-1998).

The 1997 Indonesia Demographic and Health Survey (IDHS) is a nationally representative 'community-based' survey which provides detailed information on levels and trends in fertility, mortality, and family planning; maternal and child health services and maternal mortality and knowledge of AIDS. This information together with other information from different community-based surveys and facility-based statistics are very useful in assessing the achievements and quality of interventions by the Ministry of Health.

The IDHS surveys was conducted in late 1997 covering a period in which the country is caught in number of problems including unfavorable climatic condition, due to long dry season and forest fires followed by extensive rain fall and floods, depreciation of the currency, and a wide spread political discontent. However, the survey findings show the rapid improvement of health status as a result of increased knowledge about health care and better access of health services. The findings proved that health policies and programs adopted by the Ministry of Health have been successful in improving the health condition of the public. The results of the 1997 IDHS should be disseminated to decision makers at different administrative levels and to the community at large.

In conclusion, I would like to extend my gratitude and appreciation to the Central Bureau of Statistics, the National Family Planning Coordination Board, USAID, Macro International Inc. in Maryland (USA) and all other parties who have contributed to the success of the 1997 IDHS. I believe the survey results are useful in developing future health programs.

Minister of Health
Republic of Indonesia

Prof. Dr. F.A. Moeloek

SUMMARY OF FINDINGS

The 1997 Indonesia Demographic and Health Survey (IDHS) is a nationally representative survey conducted between September and December 1997. The survey is the fourth in a series of Demographic and Health Surveys carried out in Indonesia. The first three surveys were conducted in 1987, 1991 and 1994. As in previous surveys, the main purpose of the survey was to provide policy makers and program managers in population and health with detailed information on fertility, infant and child mortality, family planning, and maternal and child health. As in the 1994 IDHS, the 1997 survey also collected household expenditure data, information necessary for the calculation of the maternal mortality rate, and data concerning knowledge of AIDS. In addition, the 1997 IDHS collected information which can be used as indicators of family welfare. Findings on the household expenditures, maternal mortality and family welfare are not presented in this report.

All of the IDHS surveys were carried out by the Central Bureau of Statistics at the request of the State Ministry for Population/National Family Planning Coordinating Board (NFPCB). Since 1991, the Ministry of Health collaborated at all stages of the project. The DHS project of Macro International Inc. provided technical assistance under a contract with the United States Agency for International Development (USAID). All of the local costs for the survey were provided by the Government of Indonesia through the NFPCB development budget.

A total of 34,255 households and 28,810 ever-married women age 15-49 were interviewed. Findings of the survey are presented at the national level, by the three regions developed for family planning program management classified by urban and rural residence, and for each of the 27 provinces in the country. The results indicate that the majority of women (87 percent) have had some formal education, and 59 percent completed primary or higher education. Half of the respondents worked in the 12 months prior the survey.

Over the last three decades, fertility in Indonesia has declined from 5.6 children per woman in 1967-1970 to 2.8 children per woman in 1995-1997. The decline in fertility varied over time, and across region. It accelerated between the late 1960s and mid-1980, and then slowed. Women in Java-Bali have the lowest total fertility rate (2.6 children per woman), while women in Outer Java-Bali I and Outer Java-Bali II have 3.1 and 3.2 children per woman, respectively. In some provinces, namely DKI Jakarta, DI Yogyakarta and Bali, fertility has reached or is approaching the replacement level. In others, the total fertility rates is still 3 children or more. Since the early 1990s, the peak of the age-specific fertility curve has shifted from women age 20-24 to women age 25-29.

One of the factors influencing fertility decline is the gradual increase in the proportion of women who stay single. Those who marry, do so at a later age. The median age at first marriage has increased from 17.3 years for women age 45-49 to 19.9 among women age 25-29. Consequently, women also start childbearing at a later age. The median age at first birth increased moderately over the last two decades from 20.5 years among women age 40-44 to 21.6 years for women age 25-29. Women in Java-Bali marry at least one year earlier than women in the Outer Java-Bali regions. Women with secondary or higher education marry four years later than women with some secondary education, and five years later than women who have no formal education.

Women's knowledge of family planning methods and sources for methods is virtually universal. While familiarity with pills and IUD remained at high levels (94 and 85 percent of currently married women, respectively), the proportion of women who have heard of injections and implants has increased substantially to 94 and 81 percent, respectively.

Fifty-seven percent of currently married women use a method of family planning and almost all of these women use a modern contraceptive method. The majority of contraceptive users use injection (21 percent of all currently married women age 15-49, or 37 percent of all current users). The next most commonly used methods are the pill (15 percent) and IUD (8 percent). As expected, women in the Java-Bali region show the highest contraceptive use (61 percent), while the lowest use is in Outer Java-Bali II (51 percent).

Private medical sources are gaining popularity in supplying modern contraceptives, and are almost drawing equal to government sources (42 percent and 43 percent, respectively). The remaining 15 percent of users obtain their methods from other sources such as village delivery posts (*polindes*), integrated health posts (*posyandu*) and family planning posts. The most often used service providers among the government sources are public health centers and among private medical sources are midwives.

The level of sustainability of the family planning program in terms of the proportion of users who pay for services is higher in 1997 than that in 1994--84 percent compared with 74 percent, respectively. In 1997, three in four contraceptive users who obtained a family planning method from a government source paid for the method.

One measure of quality of contraceptive use is the rate at which users discontinue using a method, and their reasons for doing so. Overall, 24 percent of family planning users discontinue using a method within 12 months of starting use. Of importance to family planning program managers is the fact that fear of side effects and health concerns account for 10 percent of discontinuations.

While contraceptive use continues to increase, unmet need for family planning services still accounts for 9 percent of currently married women. The unmet need is equally split between the need for spacing (4 percent) and limiting (5 percent). If the total demand for family planning were satisfied, the contraceptive prevalence rate would increase to 67 percent.

Fertility desires have not changed much in the past ten years. Half of married women do not want any more children or have been sterilized. Younger women are more likely to want to have another child, while older women tend to want to stop childbearing. If all unwanted births were avoided, the total fertility rate would be 2.4 children per woman instead of the observed 2.8 children.

Childhood mortality continues to decline. The infant mortality rate for the period approximately 1992-1997 is 46 deaths per 1,000 live births, down from 59 deaths in the period 1987-1992. The comparable decline in under-five mortality is from 83 to 58 deaths per 1,000 live births. The probability of dying in infancy is highest among births to women with no education, in rural areas, births who received no antenatal or delivery care, and those born less than two years after a preceding birth.

Nine in ten births in the five years preceding the survey received care from a medical professional during pregnancy. The most common providers of antenatal care are public health centers (39 percent) and private midwives (27 percent). More than half of pregnant women received two or more tetanus toxoid injections and three-quarters received iron tablets to reduce pregnancy-induced anemia.

Although the majority of births in Indonesia are still delivered by a traditional birth attendant (54 percent), the role of private midwives in assisting delivery has become more prominent. In 1997, midwives provided assistance to four in ten births in the five-year period before the survey.

IDHS data also indicate some improvement in vaccination coverage for children. Based on

information recorded on the health card and reported by the mothers, 55 percent of children 12-23 months have received BCG, measles, and three doses of diphtheria, pertussis, tetanus and polio vaccines. This level is higher than that recorded in the 1994 IDHS (50 percent). Low birth order children, those living in urban areas, particularly in the Outer Java-Bali II region, and children of better educated mothers are more likely to have received the complete immunization schedule.

In the two-week period preceding the survey, 9 percent of children under five were reported to have had a cough accompanied by rapid breathing, symptoms of acute respiratory illness. Seven in 10 of these children were taken to a health facility for treatment or advice.

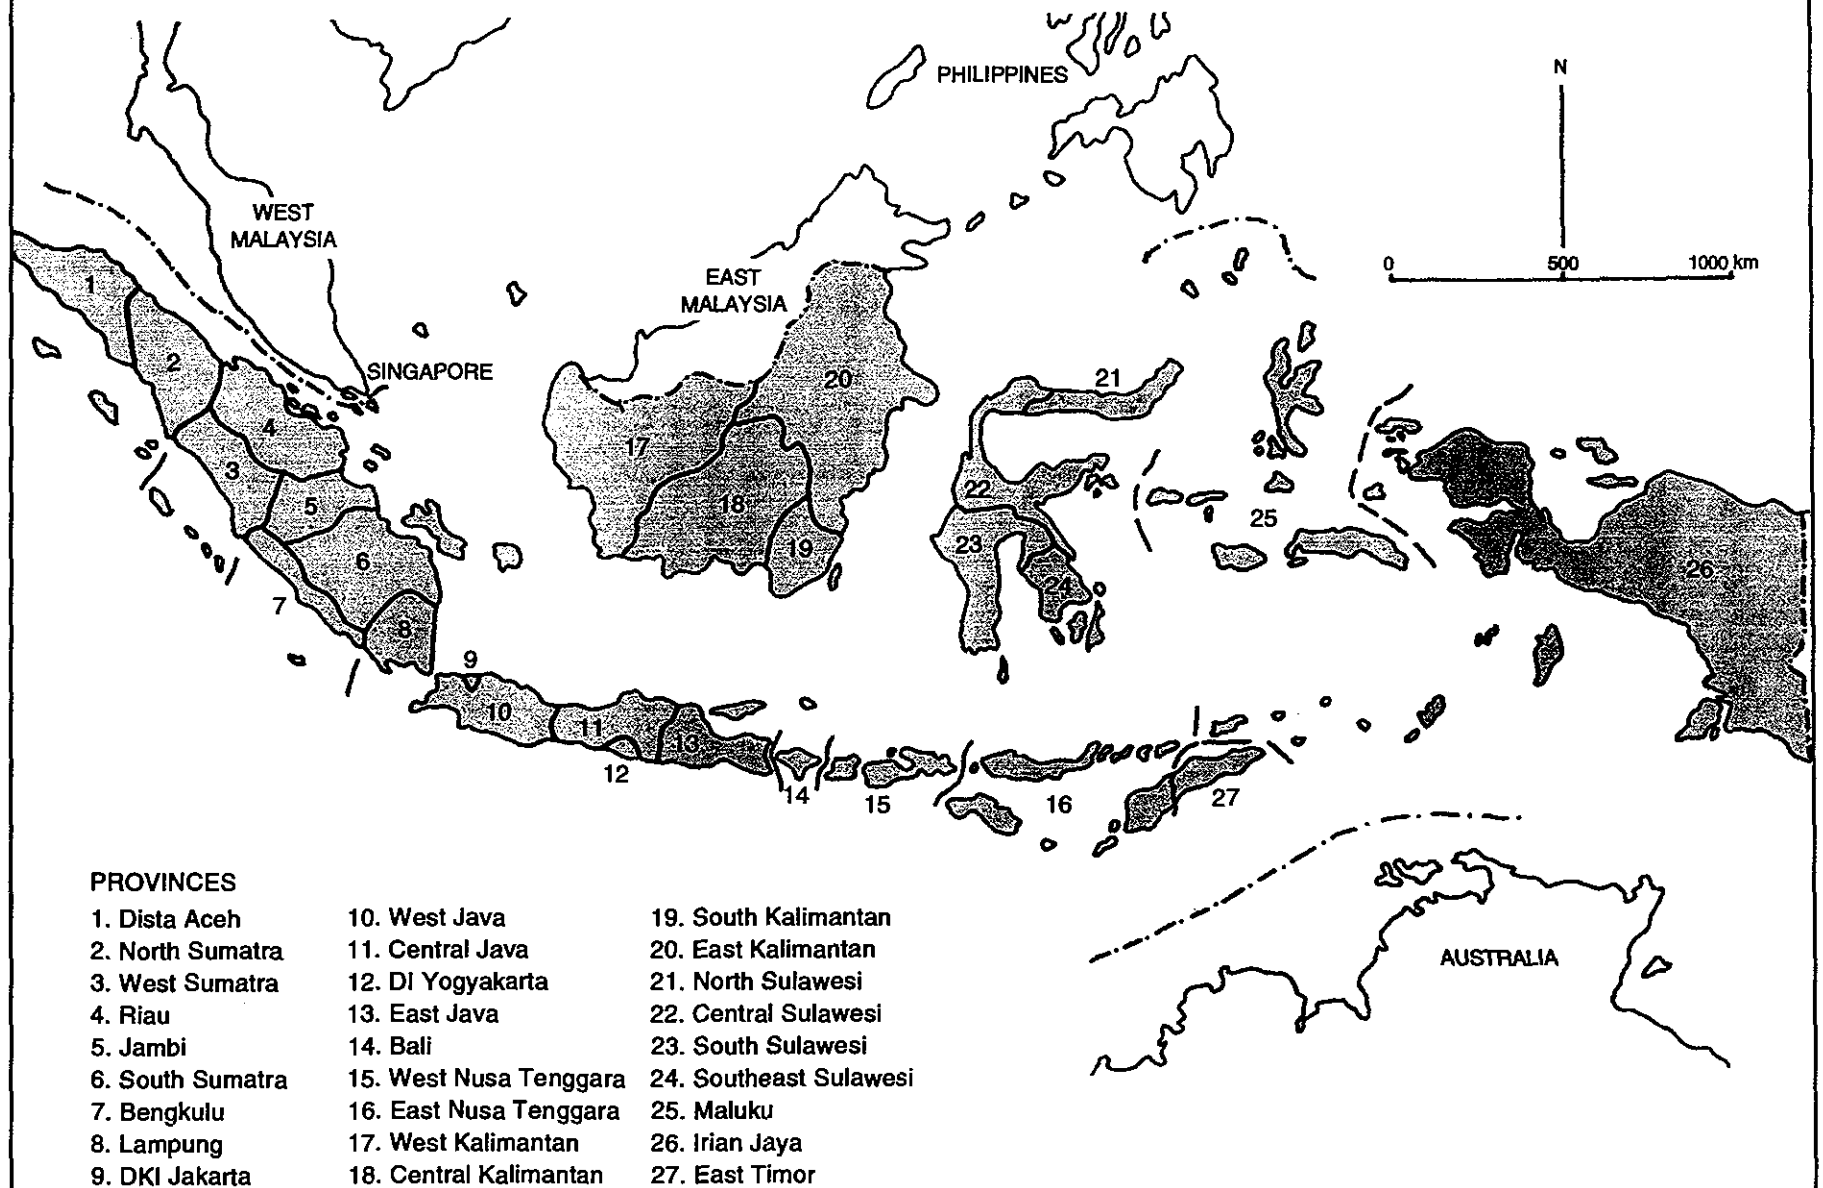

Over the same time period, 10 percent of children under five suffered from diarrhea, of whom 54 percent were taken to a health facility for treatment. Oral rehydration salts were given to 48 percent of children with diarrhea. While 57 percent of children who had diarrhea were given more fluids, the majority (76 percent) were given the same amount or less solid foods, and 80 percent of breastfed children were given the same amount or less breast milk.

One in four children under five was reported to have had a fever at some point during the two weeks before the survey. More than half of children (56 percent) of children with fever were taken to a health facility for treatment.

While the Ministry of Health recommends that infants under 4 months be given breast milk only, supplementary feeding is initiated very early. Among infants under 4 months old, in addition to breast milk, 3 percent were given plain water, 5 percent were given other liquid, 8 percent were given other milk, and 28 percent have started taking solid or mushy food. On average, children are breastfed for almost two years (24 months). Rural children, those living in Java-Bali, children whose mothers have no education and those who were assisted by a traditional birth attendant during delivery tend to be breastfed longer than other children.

More than half of ever-married women in Indonesia have heard about AIDS. Television is overwhelmingly the most important source of information about the disease. Knowledge of AIDS varies across subgroups of women. Urban women, better educated women and young women in their 20s are more likely than other women to have heard about AIDS. Most women (86 percent) who know about AIDS also know about condoms.

INDONESIA

CHAPTER 1

INTRODUCTION

1.1 Geography, History, and Economy

The Republic of Indonesia, which consists of approximately 17,000 islands, is located between 6 degrees north and 11 degrees south latitude, and from 95 to 141 degrees east longitude. The Indonesian archipelago lies between Asia and Australia. It is bounded by the South China Sea in the north, the Pacific Ocean in the north and east, and the Indian Ocean in the south and west. There are five major islands: Sumatra in the west; Java in the south; Kalimantan straddling the equator; Sulawesi, which resembles the letter "K"; and Irian Jaya bordering Papua New Guinea on the west. Two remaining groups of islands are Maluku and Nusa Tenggara, running from Sulawesi to Irian Jaya in the north, and from Bali to Timor in the south. Other islands are small and mostly uninhabited. More than 80 percent of Indonesia's territory is covered with water; the land area is about 1.9 million square kilometers. The large number of islands and their dispersion over a wide area has given rise to a diverse culture and hundreds of ethnic groups, each with its own language. This is the basis of the national motto, "Unity in Diversity."

Indonesia's climate is tropical with two seasons. The dry season extends from May to October, and the rainy season from November to April.

Indonesia is administratively divided into 27 provinces. Each province consists of *regencies* and *municipalities*. Altogether, there are 249 regencies and 65 municipalities. The next lower administrative unit is the *subdistrict*, then the *village*. Classification of urban and rural areas is made at the village level. In 1997, there were 4,028 subdistricts and 66,913 villages (7,230 urban villages and 59,683 rural villages).

Since proclaiming its independence in 1945, Indonesia has experienced several political shifts. In 1948, a rebellion by the Communist Party took place in Madiun. Up until the end of 1949, when the Dutch gave up control over Indonesia, there were disputes against the ruling democratic republic. Some factions, supported by the Dutch, formed the Federation of Indonesian Republics, which lasted less than one year. From 1950 to 1959, Indonesia faced several political problems, including the adoption of a multi-party system (which resulted in political and economic instability) and rebellions caused by ideological, ethnic and racial differences. The history of the Republic of Indonesia had a turning point after an aborted coup by the Communist Party in September 1965. In 1966, President Suharto began a new era with the establishment of the New Order Government, which was oriented toward overall development.

After more than 30 years under the New Order Government, Indonesia has made substantial progress, particularly in stabilizing political and economic conditions. A period of great economic growth was experienced from 1968 to 1986, when per capita income increased sharply from about US \$50 to US \$385. This increase was primarily the result of the international oil boom in the early 1980s, from which more than 60 percent of the country's foreign exchange came. The drop in the price of crude oil and natural gas in 1985 forced the Government to look for alternative sources of income, such as manufacturing, international trade, and service industries. This effort has been successful. Per capita income has increased to around US \$1,124 in 1996, while the economic growth was around 5 percent. All of this increase ended in mid-1997 when the Asian economy collapsed. The value of the currency plummeted, prices increased, and unemployment rose dramatically. In addition, parts of the country suffered from relatively long droughts and extensive forest fires.

An important achievement of the Indonesian government is the improvement of the general welfare of the population by ensuring the availability of adequate food, clothing, and housing, as well as providing adequate education and health services. Data from the 1971 and 1990 Population Censuses and the 1997 National Socio-Economic Survey (Susenas) show that in the past 25 years Indonesia has undergone a major improvement in the area of education. The percentage of persons age 10 years and over who were literate increased from 61 percent in 1971 to 84 percent in 1990 and to 89 percent in 1997. The improvement in education is most visible among females. Whereas school attendance among children age 7 to 12 years in 1971 was 62 percent for males and 58 percent for females, the corresponding rate for both in 1997 was 95 percent. During the same period, the percentage of persons who never attended school decreased as the percentage of graduates at all levels increased. The percentage of persons who finished primary school only increased from 20 percent in 1971 to 30 percent in 1990 and to 33 percent in 1997, while persons who attended junior high school or had higher education increased from 7 percent in 1971 to 22 percent in 1990, and to 30 percent in 1997. At all levels, the increase in education among females has been greater than that of males.

One possible effect of more girls staying in school longer is the rise in the average age at first marriage. The mean age at first marriage increased from 19.6 years in 1971 to 21.4 years in 1990; the increase was greater in urban areas than in rural areas. The increasing level of education has also provided women with greater opportunity for participation in the labor force. Labor force participation among women age 10 and over increased from 33 percent in 1971 to 41 percent in 1997. Most women work in agriculture, trade, or the service industries.

1.2 Population

According to the 1990 Population Census, the population of Indonesia was 179.4 million in 1990 and was projected to increase to 201.4 million in 1997. This would make Indonesia the fourth most populous country in the world after the People's Republic of China, India, and the United States. An estimated 55.4 million persons (31 percent of the population) were living in urban areas in 1990, compared with 73.4 million (36 percent of the population) living there in 1997.

In addition to an already large population, Indonesia has a high rate of population growth. However, this rate has declined in the last two decades. Between 1971 and 1980, the average annual rate of population growth was 2.3 percent, compared with 2.0 percent between 1980 and 1990 (see Table 1.1). The population growth rate is projected to have declined further to 1.7 percent between 1990 and 1997.

Another characteristic of Indonesia is the uneven distribution of the population among the islands and provinces. The 1990 Population Census indicates that the population density varies across regions, not only among islands, but also among provinces of the same island. Java, which covers only 7 percent of the total area of Indonesia, is inhabited by 60 percent of the country's population, making the population density of Java (814 persons per square kilometer) higher than that of other islands. By comparison, Kalimantan has a density of 17 persons per square kilometer. Comparison of provinces in Java shows that population density ranges from 12,500 persons per square kilometer in DKI Jakarta to 678 persons per square kilometer in East Java. Population density at the national level was 93 persons per square kilometer in 1990 and projected to be 104 persons per square kilometer in 1997.

Past census and survey data show that Indonesia's fertility has declined significantly since the 1960s. The crude birth rate (CBR), which was estimated at 41 births per 1,000 population in the late 1960s, declined to 36 per 1,000 in the period 1976-79, resulting in an annual percentage decline of 1.3 percent. The CBR declined further to 28 births per 1,000 population in the period 1986-89, with an average annual rate of decline of 2.1 percent between the periods 1976-79 and 1986-89. These figures suggest a more rapid decline in fertility in the more recent years. The 1997 CBR was projected to be 23 births per 1,000 population.

Table 1.1 also shows that the total fertility rate (TFR) declined from 5.6 children per woman in the period 1967-70, to 4.7 children in 1976-79, and to 3.3 children in 1986-89. The average annual decline between the periods 1967-70 and 1976-79 was 1.8 percent; between the periods 1976-79 and 1986-89 it was 2.9 percent. The TFR is projected to be 2.6 children per woman in 1997.

Table 1.1 Basic demographic indicators

Demographic indicators from selected sources, Indonesia 1971-1997

Index	1971 Census	1980 Census	1985 Intercensal Survey	1990 Census	1997 Projection ¹
Population (millions)	119.2	147.5	164.6	179.4	201.4
Growth rate (GR) ² (percent)	2.10	2.32	2.22	1.98	1.67
Density (pop/km ²)	62.4	77.0	85.0	93.0	103.5
Percent urban	17.3	22.3	26.2	30.9	36.0
Reference period	1967-70	1976-79	1981-84	1986-89	1997
Crude birth rate (CBR) ³	40.6	35.5	32.0	27.9	22.7
Crude death rate (CDR) ⁴	19.1	13.1	11.4	8.9	7.7
Total fertility rate (TFR) ⁵	5.6	4.7	4.1	3.3	2.6
Infant mortality rate ⁶ (per 1,000 births)	142	112	71	70	50
Life expectancy ⁶					
Male	45.0	50.9	57.9	57.9	62.8
Female	48.0	54.0	61.5	61.5	66.7

¹ Projected based on the 1990 Population Census and the 1995 Intercensal Population Survey

² Calculated using compound interest formula

³ Births per 1,000 population; estimated using the formula $CBR = 9.48968 + 5.55 TFR$

⁴ Deaths per 1,000 population; $CDR = CBR - GR$

⁵ Estimated based on own children method

⁶ Estimated using indirect estimation techniques

Source: Central Bureau of Statistics, 1987; 1992; 1997a, 1997b; 1998; Central Bureau of Statistics et al., 1989

The same data sources also demonstrate that there has been a significant decline in the level of mortality. An important achievement of the first long-term development plan (LTDP) spanning the period between 1969-70 and 1993-94 was the reduction of infant and child mortality, which was achieved through integrated health and family planning services. The infant mortality rate (IMR) declined from 142 deaths per 1,000 live births in 1971, to 112 per 1,000 in 1980, to 70 per 1,000 in 1990, showing an average annual rate of decline of 2.7 percent. The IMR is projected to reach 50 deaths per 1,000 live births in 1997. During the same period, the crude death rate (CDR) decreased from 19 deaths per 1,000 population in 1971 to 9 per 1,000 in 1990, resulting in an average annual rate of decline of 2.8 percent. The CDR is projected to be 8 deaths per 1,000 population in 1997.

1.3 Population and Family Planning Policies and Programs

The Government of Indonesia has devoted many of its development programs to population-related issues since President Suharto joined other heads of state in signing the Declaration of the World Leaders in 1967. In this declaration, rapid population growth was considered an obstacle to economic development. In order to carry out its population policy, the government has launched several programs, of which family planning is an important part.

Family planning activities were initiated in Indonesia in 1957 by a private organization called the Indonesian Planned Parenthood Association (IPPA), which works under the auspices of the International Planned Parenthood Federation (IPPF). IPPA provided family planning advice and services, as well as maternal and child care. In 1968, the government established a National Family Planning Institute, which was reorganized as the National Family Planning Coordinating Board (NFPCB) two years later. NFPCB is a non-departmental body, and the chairman reports directly to the President. The government of Indonesia has a strong commitment to family planning and has been working with religious and community leaders to develop programs to promote family planning.

Family planning programs were not initiated simultaneously throughout the country. In the first 5-year development plan (Repelita), which covered the period 1969-70 to 1973-74, programs began in the six provinces of Java and Bali. In the next five-year plan, the program was expanded to ten provinces outside Java-Bali, i.e. Dista Aceh, North Sumatra, West Sumatra, South Sumatra, Lampung, West Nusa Tenggara, West Kalimantan, South Kalimantan, North Sulawesi, and South Sulawesi. In the third Repelita, the programs were further expanded to include the remaining eleven provinces. The ten provinces that started family planning programs in Repelita II are called the Outer Java-Bali I Region, whereas those that started the programs in Repelita III are grouped as the Outer Java-Bali II Region.

In less than three decades, the population policy has not only contributed to reducing the fertility rate of the country by half, but is also helping to improve family welfare. One of several factors that contributes to the success of the family planning program in Indonesia has been the involvement of the community in running the programs on the notion that family planning is more than simply controlling births. In the Act No.10 passed in 1992, family planning is explicitly defined as the efforts to increase the society's concern and participation through delaying marriage, controlling births, fostering family resilience, and improving family welfare to create small, happy, and prosperous families.

Additionally, during Repelita VII, the national family planning movement will be maintained and improved. As stated in the 1998 Broad State Policy (GBHN), "The national family planning movement as one of main activities to achieve family welfare will continue to be aimed at controlling population growth through limiting births in order to achieve harmony and balance between the growth of the population and the economy to achieve more self-reliant, happy, and prosperous families." Furthermore, the 1998 GBHN stated that family planning self-reliance and institutionalization should be improved through better accessibility and quality of both contraceptive information and supply.

1.4 Health Priorities and Programs

Health Law No. 23/1992 provides a legal basis for health sector activities. It stipulates that the goal of health development is to increase the awareness, willingness, and ability of everyone to live a healthy life. The law emphasizes the decentralization of operational responsibility and authority to the local level as a prerequisite for successful and sustainable development.

In the Second 25-Year Development Plan (1994-2019), economic and human development are identified as the keys to national development and self-reliance. Following the National Guidelines on State Policy issued in 1993, the strategy adopted to improve the health and nutritional status of the population is two-pronged: to improve the quality of health services that must become affordable to all and to promote a healthy lifestyle supported by adequate housing and environmental sanitation.

The Indonesia Ministry of Health's priorities are to improve the quality and equity of services, with particular attention to the poor. In the health sector, the major objectives of the Sixth Five-Year Development Plan (Repelita VI, 1994-1998) are to:

- Strengthen preventive and promotive activities aimed at reducing maternal, infant, and child mortality and morbidity; reducing fertility; and improving nutritional status
- Improve the quality of health services and associated referral systems
- Increase the efficiency and effectiveness of services and promote improved management of health resources
- Transform public hospitals into self-supporting units through improved cost recovery
- Promote the use of high-quality generic drugs
- Provide a health card for the poorest families, entitling them to free health services
- Promote and facilitate joint public and private financing of health care services
- Encourage the private sector to finance preventive and promotive health care
- Decentralize health service management to the district level.

The government puts great emphasis on intersectoral coordination of efforts, joint responsibility of local government and the community, region-specific programs, targeting of vulnerable groups, and support of a strong information and communication program.

1.5 Objectives of the Survey

The 1997 Indonesia Demographic and Health Survey (IDHS) is a follow-on project to the 1987 National Indonesia Contraceptive Prevalence Survey (NICPS), the 1991 IDHS, and the 1994 IDHS. The 1997 IDHS was expanded from the 1994 survey to include a module on family welfare; however, unlike the 1994 survey, the 1997 survey no longer investigated the availability of family planning and health services. The 1997 IDHS also included as part of the household schedule a household expenditure module that provided a means of identifying the household's economic status. The findings on family welfare, household expenditures, as well as maternal mortality, are discussed in separate reports.

The 1997 IDHS was specifically designed to meet the following objectives:

- Provide data concerning fertility, family planning, maternal and child health, maternal mortality, and awareness of AIDS that can be used by program managers, policymakers, and researchers to evaluate and improve existing programs

- Provide data about availability of family planning and health services, thereby offering an opportunity for linking women's fertility, family planning, and child care behavior with the availability of services
- Provide household expenditure data that which can be used to identify the household's economic status
- Provide data that can be used to analyze trends over time by examining many of the same fertility, mortality, and health issues that were addressed in the earlier surveys (1987 NICPS, 1991 IDHS and 1994 IDHS)
- Measure changes in fertility and contraceptive prevalence rates and at the same time study factors that affect the changes, such as marriage patterns, urban/rural residence, education, breastfeeding habits, and the availability of contraception
- Measure the development and achievements of programs related to health policy, particularly those concerning the maternal and child health development program implemented through public health clinics in Indonesia
- Provide indicators for classifying families according to their welfare status.

1.6 Organization of the Survey

The 1997 IDHS was implemented by the Central Bureau of Statistics (CBS) at the request of the State Ministry of Population/National Family Planning Coordinating Board (NFPCB). These organizations and the Ministry of Health (MOH) collaborated in the development of the questionnaire and in the analysis and dissemination of the results. The Government of Indonesia provided all of the local costs through the NFPCB development budget. Macro International Inc. furnished technical assistance through the Demographic and Health Surveys Program (DHS), a project funded by the U.S. Agency for International Development (USAID).

A survey Steering Committee was established; it consisted of senior representatives from the State Ministry of Population/NFPCB, CBS, MOH, the National Development Planning Board (Bappenas), and the Demographic Institute at the University of Indonesia. The Technical Team, consisting of members of the same organizations, met more frequently than the Steering Committee to discuss and decide on technical issues relating to the implementation of the survey.

The CBS executed the survey and processed the data. The directors of the provincial statistical offices were responsible for both the technical and the administrative aspects of the survey in their area. They were assisted by field coordinators, most of whom were chiefs of the population statistics sections in the provincial offices.

The 1997 IDHS used three questionnaires: the household questionnaire, the questionnaire on family welfare, and the individual questionnaire for ever-married women 15-49 years old. The general household and individual questionnaires were based on the DHS Model "A" Questionnaire, which is designed for use in countries with high contraceptive prevalence. Additions and modifications to the model questionnaire were made in order to provide detailed information specific to Indonesia. The questionnaires were developed mainly in English and were translated into Indonesian. One deviation from the standard DHS practice is the exclusion of the anthropometric measurement of young children and their mothers. A separate survey carried out by MOH provides this information.

The household questionnaire includes an expenditure schedule adapted from the core Susenas questionnaire model. Susenas is a national household survey carried out annually by CBS to collect data on various demographic and socioeconomic indicators of the population. The family welfare questionnaire was aimed at collecting indicators developed by the NFPCB to classify families according to their welfare status. Families were identified from the list of household members in the household questionnaire. The expenditure module and the family welfare questionnaire were developed in Indonesian. Findings of these questionnaires were not presented in this report.

As in previous surveys, data were collected by teams of interviewers. Altogether, 284 female interviewers, 86 male field supervisors, and 86 female field editors were recruited to form 86 interview teams. They were trained for 16 days in nine training centers during June to August 1997. The field supervisors and editors received additional training in supervisory tasks and editing techniques. Data collection took place from September to December 1997. For more information about the fieldwork, see Appendix A. A list of persons involved in the implementation of the survey is found in Appendix D. The survey questionnaires are reproduced in Appendix E.

As in the 1991 and 1994 IDHS, the 1997 IDHS was conducted in all 27 provinces in Indonesia. The sample was designed to produce estimates at the national, urban-rural, regional, and provincial levels. Table 1.2 is a summary of the results of the fieldwork for the IDHS from both the household and individual interviews by urban-rural residence. In general, the response rates for both the household and individual interviews in the 1997 IDHS are high. A total of 35,362 households were selected for the survey, of which 34,656 were found. Of the encountered households, 34,255 (99 percent) were successfully interviewed. In these households, 29,317 eligible women were identified, and complete interviews were obtained from 28,810 women, or 98 percent of all eligible women. The generally high response rates for both household and individual interviews were due mainly to the strict enforcement of the rule to revisit the originally selected household if no one was at home initially. No substitution for the originally selected households was allowed. Interviewers were instructed to make at least three visits in an effort to contact the household or eligible woman.

Table 1.2 Results of the household and individual interviews

Number of households, number of interviews and response rates, according to urban-rural residence, Indonesia 1997

Result	Residence		Total
	Urban	Rural	
Household interviews			
Households sampled	10,302	25,060	35,362
Households found	10,038	24,618	34,656
Households interviewed	9,897	24,358	34,255
Household response rate	98.6	98.9	98.8
Individual interviews			
Eligible women	8,253	21,064	29,317
Interviewed women	8,117	20,693	28,810
Eligible woman response rate	98.4	98.2	98.3

CHAPTER 2

HOUSEHOLD CHARACTERISTICS AND WOMEN'S SITUATION

The main objective of this chapter is to describe the general characteristics of the sample population, which include age and sex composition, residence, education, housing facilities, and ownership of durable goods. This information is not only useful by itself but can also be used to evaluate the quality of the 1997 IDHS data and to investigate changes in social and economic conditions over time. Data in this chapter will be presented for households, persons within households, and women eligible for the individual interview. The other objective of this chapter is to describe the environment in which the respondents (ever-married women age 15-49) and their children live. Factors believed to influence nuptiality, fertility, and contraceptive behavior, as well as maternal care and child morbidity and mortality, are discussed.

2.1 Household Population by Age and Sex

The household questionnaire in the 1997 IDHS was used to list all household members, i.e., persons who usually live in the household. Information was obtained from an adult who was familiar with the characteristics of the other household members. In addition to providing a background against which various demographic processes are occurring, the age structure of the population incorporates the past history of the population.

The reliability of the age data depends on the reporting of birth dates. For persons whose year of birth was not known, age was obtained directly from the stated age. As shown in Figure 2.1, there is a preference for certain ages, particularly those ending in 0 or 5. Errors are more obvious among the population age 20 and over, partly because younger people tend to have more education than older people and are more likely to know their date of birth. To obtain the most accurate age reporting for respondents, the 1997 IDHS interviewers were instructed to (1) ask for legal documents or identity cards, (2) relate the respondent's age to the age of another household member whose age was known or to a household event whose date had been ascertained, or (3) relate the respondent's age to local or national events well known in the area. A chart used to convert reported dates from the Javanese, Sundanese, and Muslim calendars to the Gregorian calendar was appended to the interviewers' manual. The Javanese and Sundanese calendars are actually the same as the Muslim calendar except for the names of the months.

Table 2.1 and Figure 2.2 present the age distribution of the population by five-year age groups according to sex. Age composition is affected by past levels of fertility, mortality, and migration. The population pyramid has a narrow top and a wide base, reflecting a pattern typical of countries with relatively high fertility in the past. The narrowing at the base was brought about by a decline in fertility in the past decade.

2.2 Population by Age from Other Sources

The percent distribution of the 1997 IDHS sample population by age group is presented in Table 2.2, along with comparable data from the 1980 Census, the 1985 Intercensal Population Survey (SUPAS), the 1987 National Indonesia Contraceptive Prevalence Survey (NICPS), the 1991 IDHS, and the 1994 IDHS. The percentage of the population under 15 years has decreased over time from 41 percent in 1980 to 34 percent in 1997. During the same period, the percentage of the population age 15-64 increased from 56 percent in 1980 to 62 percent in 1997. The dependency ratio, calculated as the ratio of nonproductive persons (under age 15 and age 65 and over) to persons age 15-64, has been decreasing gradually from 79 percent in 1980 to 62 percent in 1997. The smaller dependency ratio indicates a lessening of the economic burden on persons in the productive age groups who support those in the nonproductive age groups.

Dependency ratio	79	73	69	67	66	62

2.3 Household Composition

Table 2.3 presents the percent distribution of households by various characteristics, such as sex of the head of the household, size of the household, and presence of foster children. The size and composition of the household may affect the allocation of financial resources among household members, which in turn would affect the overall well-being of the members. Household size may be associated with crowding in the dwelling, which can lead to unfavorable health conditions. Single-parent families, especially if they are headed by females, usually have limited financial resources.

Table 2.3 Household composition

Percent distribution of households by sex of head of household, household size, and whether household includes foster children, according to urban-rural residence, Indonesia 1997

Characteristic	Residence		Total
	Urban	Rural	
Household headship			
Male	86.5	88.3	87.8
Female	13.5	11.7	12.2
Total	100.0	100.0	100.0
Number of usual members			
1	6.1	4.3	4.8
2	10.6	11.9	11.5

4	20.3	22.7	22.1
5	18.5	17.7	18.0
6	12.1	10.8	11.1
7	6.9	5.9	6.2
8	3.7	2.9	3.2
9+	4.2	2.5	3.0
Total	100.0	100.0	100.0
Mean size	4.5	4.3	4.3
Percent with foster children	4.7	6.1	5.7

Note: Table is based on de jure members, i.e., usual residents.

The 1997 IDHS shows that 12 percent of households are headed by women. The proportion is slightly higher in urban than in rural areas (14 percent, compared with 12 percent). Seven in ten households have between two and five members. The average household size is 4.3 persons, 4.5 persons in urban areas, and 4.3 persons in rural areas. Six percent of households include one or more children under age 15 who are living with neither their natural father nor their natural mother.

2.4 Level of Education of the Household Population

Educational attainment is closely associated with other socioeconomic factors and demographic behavior such as income, lifestyle, reproductive behavior, use of contraception, health status of children, and housing conditions. Education also influences the individual's views, and can open the mind to new ideas and technology.

Tables 2.4.1 and 2.4.2 indicate that among both men and women there are significant differences in level of education, by background characteristics. Overall, men are slightly better educated than women: nine in ten men have had some schooling compared with eight in ten women. In addition, while 34 percent of men have had some secondary education, the corresponding figure for women is 27

percent. The proportion of men and women who have only some primary schooling is almost the same, 34 percent each, and the proportion of men and women who completed only primary education is 21 percent and 20 percent, respectively. The gap in educational attainment is no longer visible among the youngest age cohort. Among boys and girls age 5-14, the median duration of schooling is very similar—1.0 and 1.2 years, respectively, for children age 5-9, and 5.3 and 5.5 years, respectively, for children age 10-14. These figures imply that in recent years, girls have had as much opportunity as boys to pursue education.

Tables 2.4.1 and 2.4.2 also show that educational attainment is negatively associated with age; older persons are more likely to have no education and to stay in school for shorter periods. For example, the median duration of schooling among men age 50-54 years is 6.2 years, whereas for men age 20-24 the median is 9.2 years. The difference for women is even more striking; 2.1 years for age 50-54 years and 7.0 years for age 20-24. Urban residents are much more likely to attend school and stay in school than residents of rural areas. Only 5 percent of men in urban areas have never gone to school, while the proportion in rural areas is more than double (13 percent). For women, the corresponding figures are 11 percent in the urban areas and 23 percent in the rural areas. The urban-rural difference is more pronounced at the level of secondary or higher education. The median years of schooling for urban men is 8.0 years, compared with 5.9 years for rural men. Urban women spend 2.4 years longer in school than their rural counterparts (6.8 years and 4.4 years, respectively).

Table 2.4.1 Educational level of the household population by background characteristics: men

Percent distribution of the de jure male household population age five and over by highest level of education attended, and median number of years of schooling, according to selected background characteristics, Indonesia 1997

¹ Includes cases with missing values on age.

Tables 2.4.3 and 2.4.4 present the differentials in educational attainment by region and province for men and women, respectively. The median duration of schooling for men is longer than that for women in all provinces except in North Sulawesi. In general, there are no significant differentials in median years of schooling of men by region (see Table 2.4.3). Table 2.4.4 shows that for women, the median duration of schooling is shortest in Java-Bali (5.4 years), while in Outer Java-Bali it is 5.8 years or longer.

Level of education varies between provinces in Java-Bali. Men and women in DKI Jakarta have the longest duration of schooling (9.5 years and 7.9 years, respectively), while Central Java has the shortest median for men (6.1 years), and East Java has the shortest duration for women (4.6 years).

Total¹	19.4	33.7	19.5	27.4	100.0	66,479	5.6

¹ Includes cases with missing values on age.

In Outer Java-Bali I, for both men and women, West Nusa Tenggara shows the lowest median duration of schooling (4.8 years for men and 3.7 years for women). The highest median duration of schooling for men is in North Sumatra (6.5 years) and in North Sulawesi for women (6.5 years). The provincial differentials in median duration of schooling in Outer Java-Bali I are not as large for men as for women (1.7 years versus 2.8 years).

Among provinces in Outer Java-Bali II, the highest median duration of schooling is in East Kalimantan—6.9 years for men and 6.4 years for women. The median duration of schooling is relatively low in East Timor—2.9 years for men and 1.6 years for women.

2.5 School Enrollment

Table 2.5 shows the percentage of the household population age 5 to 24 years enrolled in school, according to age, sex, and residence. The data confirm the findings presented in Tables 2.4.1 and 2.4.2; differences between boys and girls at the younger age groups are minimal (see Figure 2.3). While only two in five children age 5-6 are in school, almost all children age 7-12 are enrolled in school. This reflects the result of the 6 years of compulsory education that was initiated in the first Long-Term Development Plan (1969-70 to 1993-94). The proportion decreases for the older age groups. Table 2.5 indicates that at all ages, school enrollment rates are higher in urban than in rural areas.

School enrollment rates have generally increased in recent years. For example, the proportion of children age 7-15 enrolled in school has increased from 83 percent in 1994 to 87 percent in 1997 (CBS et al., 1995:19).

2.6 Housing Characteristics

Table 2.6 presents the distribution of households by selected housing characteristics, such as the source of drinking water, type of sanitation facilities, type of flooring, and distance between the well and the cesspool. These are important determinants of the health status of household members, particularly children. They can also be used as indicators of household socioeconomic status. Proper hygiene and sanitation practices can help to prevent major childhood diseases, such as diarrhea.

Overall, 80 percent of the households covered in the 1997 IDHS have electricity, a large increase from the 63 percent found in 1994 (CBS et al., 1995:21). There are significant urban-rural and regional differentials (see Figure 2.4). In urban areas, virtually all households have electricity, compared with 73 percent in rural areas. While 89 percent of households in Java-Bali have electricity, in Outer Java-Bali I the proportion is about 69 percent, and in Outer Java-Bali II it is only 55 percent.

Wells are the main source of drinking water for almost half of the households in the 1997 IDHS sample. Water that is either piped into the residence or into the yard or obtained from the public tap is used by 18 percent of households: 42 percent in urban areas and 8 percent in rural areas. Other sources of drinking water include springs, either protected or unprotected (15 percent), and pump (13 percent). Rural households are much more likely to use spring water than urban households (21 percent, compared with 1 percent, respectively). On the other hand, pumps are more common in urban areas (23 percent) than in rural areas (9 percent). Rivers, streams, and rainwater are the main sources for one-fifth of households in Outer Java-Bali II, one-tenth of households in Outer Java-Bali I, and 3 percent of households in Java-Bali.

Figure 2.4
Housing Characteristics by Residence

Note: Piped water includes public tap

IDHS97

The data in Table 2.6 indicate that for more than half of households, the source of drinking water is on the premises, while for 23 percent the source is less than 10 minutes away, and for 20 percent of the households the source is 10 or more minutes away. Urban households generally are closer to the source of drinking water than rural households. While 82 percent of households in urban areas have water on the premises and 13 percent are within 10 minutes of the source, in rural areas the corresponding figures are 47 percent and 27 percent, respectively. Households in Java-Bali and in Outer Java-Bali I are generally closer to the source of drinking water than households in Outer Java-Bali II. While more than half of households in Java-Bali and in Outer Java-Bali I have water on the premises, in Outer Java-Bali II the corresponding proportion is less than 40 percent.

Half of households have a private toilet, 11 percent use a shared facility, and the remaining 40 percent do not have a toilet. The majority of people who do not have a toilet facility go to a river, stream, or creek. The difference between urban and rural areas is significant. Overall, 71 percent of households in urban areas have a private toilet, compared with 41 percent in rural areas. Basically, the distribution of households by type of toilet facility among regions are almost the same, except for the proportion of households that go to a river, stream, or creek (almost one-third of households in Java-Bali and around one-fifth of households in Outer Java-Bali I and in Outer Java-Bali II).

Table 2.6 presents the distribution of households by the distance from the well to the nearest cesspool. Overall, for 15 percent of the households, the nearest cesspool is less than 10 meters from their well, while for 13 percent the nearest cesspool is between 10 and 14 meters, and for 16 percent the nearest cesspool is 15 meters or further from the well. In general, wells are slightly closer to cesspools in urban areas than in rural areas, and in Java-Bali and Outer Java-Bali I than in Outer Java-Bali II.

More than half of households in Indonesia live in dwellings with a concrete, brick, or tile floor, while 15 percent have a wood floor, and 22 percent have a dirt floor. There are substantial urban-rural differentials

by floor materials. Whereas 71 percent of urban households have a concrete, brick, or tile floor, the proportion in rural areas is 47 percent. Conversely, 29 percent of rural households have a dirt floor, compared with 5 percent in urban areas. There are also substantial regional variations. In Java-Bali, the majority of the households (58 percent) have concrete or tile floors, while in the Outer Java-Bali regions it is less than 50 percent. In the Outer Java-Bali regions, wood is commonly used as floor material (34-35 percent).

Seven in ten households live in dwellings with 10 square meters or more of floor space. The difference between urban and rural households is not significant (71 percent and 72 percent, respectively). However, households in Java-Bali in general have more space than those in other regions do. Almost half of households in Outer Java-Bali II live in houses with less than 10 square meters of floor area.

2.7 Household Durable Goods

The presence of durable goods in the household, e.g., radio, television, motorcycle, and private car, is an indicator of the household's socioeconomic status. Table 2.7 shows that 62 percent of households have a radio, 48 percent have a television, 11 percent have a refrigerator, 48 percent have a bicycle or boat, and 21 percent have a motorcycle or motorboat. Only 4 percent of households have a private car. About 20 percent of households have none of the durable goods listed in Table 2.7.

Urban-rural differentials can be seen in the ownership of specific durable goods. In general, these goods are more available in urban households than in rural households. For example, three in four urban households have a television set, while in rural areas the proportion is only 37 percent. A refrigerator is available in 30 percent of urban households, but it is almost nonexistent in rural areas. Urban households are five times more likely to own a private car than rural households.

Table 2.7 Household durable goods

Percentage of households possessing various durable consumer goods, by urban-rural residence, Indonesia 1997

Durable goods	Residence		Total
	Urban	Rural	
Radio	74.5	56.7	61.8
Television	74.5	37.3	47.9
Refrigerator	30.2	3.8	11.3
Bicycle/Boat	48.1	47.2	47.5
Motorcycle/Motorboat	30.8	16.5	20.6
Private car	10.1	2.0	4.3
None of the above	10.9	23.4	19.8
Number of households	9,787	24,468	34,255

2.8 Respondents' Background Characteristics

Table 2.8.1 presents the distribution of ever-married women age 15-49 by selected background characteristics along with the actual and weighted number of eligible women interviewed. The weighting is necessary to compensate for differences in the selection probabilities and response rates, and to make the regional and urban-rural distribution of the sample correspond to that expected from official sources. All results presented in this report are weighted.

The distribution of ever-married women by age group is similar to that for the 1987 NICPS, the 1990 Population Census, and the 1991 and 1994 IDHS. The majority of respondents are age 25-39 (56 percent), while less than 5 percent are age 15-19, and about 12 percent are age 45-49. Ninety-three percent of the women in the sample are currently married; the remaining 7 percent are either divorced or widowed. Seventy-two percent of respondents live in rural areas and 28 percent in urban areas.

Thirteen percent of the survey respondents have never attended school, 28 percent have some primary education but did not finish primary school, 31 percent stopped after completing primary school, and 28 percent have some secondary or higher education. A majority of the women surveyed are Muslim (90 percent), 8 percent are Protestant or Catholic, 2 percent are Hindu, and less than one percent are Buddhist.

Table 2.8.2 presents the weighted and unweighted distribution of the respondents by region and province. The table shows that the majority of respondents (63 percent) live in Java-Bali, while 26 percent live in Outer Java-Bali I, and 11 percent live in Outer Java-Bali II. The provinces of East Java and West Java account for 20 percent of respondents each; 16 percent reside in Central Java.

2.9 Respondents' Level of Education by Background Characteristics

The distribution of respondents by education and selected background characteristics is presented in Table 2.9.1. Comparison across cohorts shows that urban and younger women are more likely to have higher education than their rural and older counterparts. For example, while 27 percent of women age 45-49 never went to school, the proportion among women 15-19 is less than 3 percent. On the other hand, three-quarters of women age 15-19 have completed primary school, compared to only 39 percent of women in the oldest age group. Only 5 percent of respondents in urban areas have not attended school; in rural areas the percentage is 16 percent. By contrast, half of urban women have attended secondary school, compared with 19 percent in rural areas.

There is no significant variation in women's educational attainment across regions. Comparison of women's educational attainment by province, however, reveals more pronounced variations (see Table 2.9.2). The proportion of women who have never gone to school varies from less than 5 percent in North Sulawesi, West Sumatra, DKI Jakarta, Central Sulawesi, and Maluku, to more than 20 percent in Bali, West Kalimantan, West Nusa Tenggara, Irian Jaya, and East Timor. In the latter province, 54 percent of women have had no formal education.

2.10 Access to Mass Media

The availability of mass media (newspaper, television and radio) is presented in Table 2.10.1. One in four respondents read the newspaper weekly, more than three in four watch television weekly, and one in two listen to the radio every day. While one in six have access to all three mass media, the same proportion are exposed to none of these mass media. Younger women, women in urban areas, and better educated women are more likely to have access to mass media than other women are. For example, 92 percent of urban women watch television, while the proportion in rural areas is 73 percent; 26 percent of urban women are exposed to all three media, while in rural areas only 11 percent are. There is a positive association between level of education and exposure to mass media: as education increases, access to mass media increases. The same pattern was found in the 1991 IDHS and the 1994 IDHS (CBS et al., 1992 and CBS et al., 1995).

Table 2.10.2 shows the percentage of women who have access to mass media according to region and province. While women in Java-Bali are more exposed to television than women in Outer Java-Bali, women in Outer Java-Bali II are more exposed to newspaper than women in other regions, and women in Outer Java-Bali I are more exposed to radio broadcast than women in other regions. Women in DKI Jakarta are the most likely to watch television (97 percent), followed by East Kalimantan (94 percent), and DI Yogyakarta (90 percent). At the other extreme, women in East Nusa Tenggara are least likely to watch television (24 percent).

2.11 Employment

In the 1997 IDHS, respondents were asked if they worked aside from doing their housework, regardless of whether they were paid or not. Table 2.11.1 shows that one in two women were engaged in an economic activity in the last 12 months. Older women, women in rural areas, and women who have no education are more likely to have been employed. For example, the proportion of women 35 years or older who worked is around 60 percent, while for women under 25 the proportion is under 35 percent. The smaller proportion of young women who work may be related to the problem of securing child care, while urban and better educated women are generally younger and thus less likely to work.

Table 2.9.1 Level of education: background characteristics

Percent distribution of ever-married women by the highest level of education attended, according to selected background characteristics, Indonesia 1997

Background characteristic	Highest level of education				Total	Number of women
	No education	Some primary	Completed primary	Some secondary +

Region/Residence						
Java-Bali	13.8	27.9	33.7	24.6	100.0	18,039
Urban	5.4	18.7	28.9	47.0	100.0	5,722
Rural	17.7	32.2	35.9	14.2	100.0	12,317
Outer Java-Bali I	11.8	28.2	26.0	34.0	100.0	7,550
Urban	4.2	15.2	21.8	58.7	100.0	1,625
Rural	13.9	31.7	27.2	27.2	100.0	5,925
Outer Java-Bali II	13.5	24.9	28.4	33.2	100.0	3,221
Urban	3.8	16.9	19.1	60.3	100.0	686
Rural	16.2	27.0	30.9	25.9	100.0	2,534
Total	13.2	27.7	31.1	28.0	100.0	28,810

Table 2.11.2 shows that more than 70 percent of women in DI Yogyakarta, Bali, and Bengkulu worked in the 12 months preceding the survey. In contrast, low proportions (less than 40 percent) of working women are found in West Java, North Sulawesi, South Sulawesi, East Timor, and Maluku.

2.12 Occupation

Table 2.12.1 presents the percent distribution of women who worked in the 12 months prior to the survey by occupation, according to selected background characteristics. Forty-four percent of the women worked in agriculture, among whom seven in ten worked on their own land. The table also shows that for women who work outside the agricultural sector, sales is a popular choice of employment (25 percent), followed by manufacturing industries (17 percent), services (6 percent), and professional and technical occupations (5 percent).

Women's occupations vary by age. The proportion of women who worked in agriculture is highest for those in the youngest and oldest age groups. The proportion declines from 53 percent of working women age 15-19 to 41 percent of women age 30-39, and it increases to 55 percent for women age 45-49. On the other hand, the proportion of women working as professional and technical workers, has an opposite pattern: low at younger ages, peaking at age 30-34, and then declining for older women. Manufacturing industries attract younger women.

Table 2.9.2 Level of education: region and province

Percent distribution of ever-married women by the highest level of education attended, according to region and province, Indonesia 1997

Region and province	Highest level of education attended				Total	Number of women
	No education	Some primary	Completed primary	Some secondary +		
Java-Bali	13.8	27.9	33.7	24.6	100.0	18,039

South Kalimantan	8.5	30.9	27.2	33.4	100.0	433
North Sulawesi	1.4	26.9	20.4	51.4	100.0	340
South Sulawesi	16.2	25.2	27.5	31.1	100.0	1,049
Outer Java-Bali II	13.5	24.9	28.4	33.2	100.0	3,221
Riau	13.9	30.7	23.4	32.0	100.0	477
Jambi	17.9	20.1	35.3	26.7	100.0	416
Bengkulu	10.1	36.1	19.9	33.9	100.0	192
East Nusa Tenggara	15.6	23.4	37.8	23.3	100.0	489
East Timor	53.9	16.7	8.7	20.7	100.0	120
Central Kalimantan	7.7	27.3	34.1	30.9	100.0	238
East Kalimantan	6.4	27.2	21.5	44.9	100.0	363
Central Sulawesi	3.9	21.4	37.6	37.1	100.0	270
Southeast Sulawesi	9.5	23.6	25.5	41.6	100.0	178
Maluku	4.4	22.7	27.8	45.1	100.0	235
Irian Jaya	22.4	21.4	20.0	36.4	100.0	242
Total	13.2	27.7	31.1	28.0	100.0	28,810

Table 2.12.1 shows that women's occupations vary significantly by urban-rural residence and education. While 57 percent of working women in rural areas are engaged in the agricultural sector, the corresponding proportion in urban areas is 5 percent. In contrast, urban women are more likely to work in sales (43 percent), manufacturing industries (18 percent), services (15 percent), and professional and technical jobs (9 percent). The urban-rural differentials in all regions are similar to those at the national level.

Women's education is inversely related to their propensity to work in agriculture; employed women with no education are much more likely to be working in agriculture than better educated women. For example, 65 percent of working women with no education worked in agriculture, compared with only 16 percent of women who have attended secondary school. In contrast, women who are better educated are more likely to be employed in sales, industrial, professional and technical, and clerical occupations.

Table 2.10.1 Access to mass media: background characteristics

Percentage of women who usually read a newspaper once a week, watch television once a week, or listen to the radio daily, by selected background characteristics, Indonesia 1997

Some secondary +	3.6	57.2	91.8	57.3	34.5	8,090
Total	14.7	25.0	77.9	49.4	15.5	28,810

Table 2.12.2 shows differences among provinces in respondents' patterns of work. In DKI Jakarta, virtually all women who work are employed in the nonagricultural sector. In this province, two in five working women work in sales, 23 percent in services, 16 percent in industry, and 13 percent in clerical jobs. Relatively large proportions of women work in industrial occupations in most provinces in Java-Bali, while professional and technical professions are more popular in North Sulawesi than in other provinces. Three-quarters or more of working women in West Kalimantan, Jambi, and East Nusa Tenggara work in agriculture.

2.13 Decisions on Use of Earnings

When assessing the status of women, one valuable indicator is their independence in making decisions on the use of their earnings. Table 2.13.1 shows that more than half (51 percent) of employed women make their own decisions on the use of their earnings, while 44 percent decide together with their husband, and 5 percent are not involved in making the decisions. Independent decision making on use of earnings tends to be higher among older women, women in urban areas, those living in the Java-Bali region, and among formerly married women.

Table 2.10.2. Access to mass media: region and province

Percentage of women who usually read a newspaper once a week, watch television once a week, or listen to the radio daily, by region and province, Indonesia 1997

Total	14.7	25.0	77.9	49.4	15.5	28,810

Table 2.13.2 shows that the percent distribution of employed women, according to who decides on use of their earnings, varies significantly by province. The percentage of women who make their own decisions on the use of their earnings varies from 15 percent in Bali to 72 percent in South Sulawesi. For women who make the decision together with their husbands, the percentage varies from a low of 23 percent (Southeast Sulawesi) to a high of 81 percent (Bali). One in five women in West Kalimantan and Irian Jaya and one in eight women in West Sumatra report that their husbands alone decide on how to spend their earnings; in the remaining provinces the percentages are below 10 percent.

2.14 Child Care While Working

The welfare of children under five years of age whose mothers are employed is the focus of Table 2.14.1. Overall, one in three women who worked in the 12 months prior to the survey have one or more children under age five. This proportion varies by residence, education, and occupation. Better educated women, and women who work occasionally are more likely to have children under five. As a reflection of regional fertility differentials, women in Java-Bali are less likely to have children under age five than women on the other islands.

Table 2.11.2 Employment: region and province

Percent distribution of women by employment status in the last 12 months, according to region and province, Indonesia 1997

Region and province	Did not work in last 12 months	Worked in last 12 months	Total	Number of women

Total	50.3	49.7	100.0	28,810

Among working women with young children, 41 percent take care of their children while they work. Relatives and older female siblings are the most common caretakers for children of working women (37 percent and 10 percent, respectively). The role of female siblings in child care is significant in families where the mother has limited education, works in agriculture, or works as a seasonal worker. Children whose mothers have attended secondary school, live in urban areas, are professionals, or work in clerical occupations, are more likely to be cared for by servants or hired help. Across all subgroups, husbands and male siblings have a very limited role in child minding while the mother is at work (3 and 2 percent, respectively).

Table 2.12.1 Occupation: background characteristics

Percent distribution of women employed in the 12 months before the survey by occupation and type of agricultural land worked or type of non-agricultural employment, according to selected background characteristics, Indonesia 1997

The proportion of working mothers with children under five varies between a low of less than 30 percent in DKI Jakarta, DI Yogyakarta, East Java, and North Sulawesi, to 58 percent in East Timor (see Table 2.14.2). With some exceptions, mothers, relatives and female siblings are the most important care givers while the mother is working. Servants or hired help are popular in DKI Jakarta, where they care for almost one in five children under age five.

Table 2.12.2 Occupation: region and province

Percent distribution of women employed in the 12 months before the survey by occupation and type of agricultural land worked or type of non-agricultural employment, according to region and province, Indonesia 1997

CHAPTER 3

FERTILITY

A major objective of the 1997 IDHS is to estimate fertility levels, trends and differentials. As with the 1991 and 1994 IDHS; detailed information on current, cumulative and past levels of fertility was collected in the 1997 IDHS from ever-married women. The fertility information was collected using two procedures. First, each woman was asked a series of questions about the number of live births she had ever had and the number of children surviving. Experience has indicated that certain types of events are underreported. To minimize error, children were identified by sex, whether they lived with their mother or elsewhere, and by whether they were living or dead. Identification by sex improves reporting and allows estimation of sex-specific mortality rates.

Second, a full birth history was obtained from each woman, and for each live birth the following information was collected: name, sex, month and year of birth, whether the birth was single or multiple, and the survival status of the child. For living children, the woman was asked whether the child was living in the household or away. For dead children, the age at death was recorded. To reduce underreporting of births when the interval between births was 4 years or longer, interviewers were required to check whether the respondent had had a child during the interval. Information on whether currently married women were pregnant was also solicited.

From population censuses and surveys in Indonesia, fertility and mortality rates have been estimated using indirect methods, based on information on the number of children ever born and children surviving. The fertility measures presented here are calculated directly from the birth history. In applying a direct fertility estimation procedure, it is important to note that although the birth history offers a richer set of data for analysis, there are some limitations. Because interviews were conducted only with living women, there was no information on the fertility of women who had died. The fertility rates would be biased if the mortality of women of childbearing age were high and if there were significant differences in fertility between living and dead women. In Indonesia, neither of these appears to be the case. Also, the 1997 IDHS collected birth histories only from ever-married women. Since most births in Indonesia occur within marriage, the number of births to single women is negligible.

The accuracy of fertility data is affected primarily by underreporting of births (especially children who died in early infancy) and misreporting of date of birth. Errors in underreporting of births affect the estimates of fertility levels, while misreporting of dates of births can distort estimates of fertility trends. If these errors vary by socioeconomic characteristics of the women, the differentials in fertility will also be affected.

3.1 Fertility Level and Trends

Table 3.1 and Figure 3.1 present the total fertility rates (TFR) and the age-specific fertility rates (ASFR)¹ derived from the 1997 IDHS, along with results from previous data sources. The TFR is calculated

¹Numerators of the age-specific fertility rates are calculated by summing the number of live births that occurred in the period 1-36 months preceding the survey (determined by the date of interview and the date of birth of the child), and classifying them by the age (in 5-year groups) of the mother at the time of birth (determined by the mother's date of birth). The denominators of the rates are the number of woman-years lived in each of the specified 5-year groups during the 1 to 36 months preceding the survey. Since only women who had ever married were interviewed in the IDHS, the numbers of women in the denominators of the rates were inflated by factors calculated from information in the household questionnaire on proportions ever married in order to produce a count of all women. Never-married women are presumed not have given birth.

Table 3.1 Fertility rates from various sources

Age-specific and cumulative fertility rates from selected sources, Indonesia 1971-1994

Age group	1971 Census (1967-70)	1976 SUPAS (1971-75)	1980 Census (1976-79)	1985 SUPAS (1980-85)	1987 NICPS ¹ (1984-87) ²	1990 Census (1986-89)	1991 1991 (1988-91) ²	1994 IDHS (1991-94)	1997 IDHS (1995-1997) ²		
									Urban	Rural	Total

TFR 15-44	5.52	5.11	4.62	4.01	3.34	3.27	2.99	2.83	2.39	2.94	2.76
GFR	-	-	-	-	-	-	108	101	83.0	104.0	97.0
CBR	-	-	-	-	-	-	25.1	23.3	22.0	23.6	23.1

Note: Estimates for 1971 through 1985 and for 1990 were computed using the own children method, while the 1987 NICPS, 1991 IDHS and 1994 IDHS rates were calculated directly from birth history data.

TFR: Total fertility rate expressed per woman

GFR: General fertility rate (births divided by number of women 15-44), expressed per 1,000 women

CBR: Crude birth rate expressed per 1,000 population

¹ Excludes 7 provinces in Outer Java-Bali II

² 1-36 months prior to survey

Figure 3.1
Age-Specific Fertility Rates
Indonesia, 1967-1997

IDHS97

by summing the age-specific fertility rate and can be interpreted as the average number of births a hypothetical woman would have at the end of her reproductive life if she were subject to the currently prevailing age-specific rates from 15 to 49. It is important to note that the rates are not strictly comparable because of differences in data collection procedures, geographic coverage, and estimation techniques. Nevertheless, they serve the purpose of reflecting recent fertility trends in Indonesia.

Table 3.1 shows that while the TFR continues to decline, the pace has slowed. The current level of fertility (2.8 births per woman) is half of what was reported for the 1967-1970 period (5.6 births per woman).

Results from the 1997 IDHS indicate that the age pattern of fertility by age group is the same as that in the 1994 IDHS; the peak (149 births per 1,000 women) is for women age 25-29. For urban residents, the age-specific fertility rate peaks at age 25-29, while for rural women the peak is at age 20-24. The 1997 IDHS data indicate that there is a gap in fertility between urban and rural residents. Urban women have, on average, 0.6 children fewer than rural women (2.4 compared with 3.0, respectively). The largest urban-rural difference is for women age 15-24.

Table 3.1 also presents the general fertility rate (GFR) and the crude birth rate (CBR) for the three years preceding the survey. The GFR is the number of live births per 1,000 women age 15-44. The CBR is the number of births per 1,000 population; it is calculated by summing the product of the age-specific fertility rates and the proportion of women in the specific age group out of the total number of persons who usually live in the selected households. The GFR is 97 and the CBR is 23.

Fertility trends can also be investigated using retrospective data from a single survey. Table 3.2 is generated from the birth history data collected in the 1997 IDHS. The numerators of these rates are classified by four-year segments of time preceding the survey and by mother's age at the time of birth in five-year intervals. Since women 50 years and over were not interviewed in the 1997 IDHS, the data in Table 3.2 is truncated. For example, rates cannot be calculated for women age 45-49 for part of the 4-7 years and all of the 8-11 years prior to the survey, because these women would have been 50 years or older at the time of the survey. The bottom diagonal of estimates is also partially truncated.

Table 3.2 Age-specific fertility rates

Age-specific fertility rates for four-year periods preceding the survey, by mother's age at the time of birth, Indonesia 1997

Maternal age at birth	Number of years preceding the survey				
	0-3	4-7	8-11	12-15	16-19
15-19	62	79	81	117	127
20-24	145	159	175	220	240
25-29	148	156	172	203	236
30-34	107	125	125	162	[196]
35-39	65	66	86	[112]	-
40-44	27	34	[69]	-	-
45-49	[5]	[22]	-	-	-

Note: Age-specific fertility rates are per 1,000 women. Estimates in brackets are truncated.

As shown in the table for all age groups, the decline is steepest between the periods 12-15 and 8-11 years before the survey. For most age groups, this is followed by a plateau or less steep decline between the periods 8-11 and 4-7 years ago, and then by a steeper decline between 4-7 and 0-3 years ago.

Table 3.3 presents trends in fertility by marital duration. This table shows the same pattern as in Table 3.2; for the same age group or marriage duration, recent fertility is lower than that in the distant past, and fertility has declined most rapidly in the period 12-15 to 8-11 years before the survey.

Table 3.3 Fertility by marital duration

Fertility rates by duration (years) since first marriage for four-year periods preceding the survey, Indonesia 1997

Marital duration at birth	Number of years preceding the survey				
	0-3	4-7	8-11	12-15	16-19
0-4	271	282	282	317	313
5-9	153	170	184	222	269
10-14	113	125	145	184	210
15-19	75	96	107	146	[185]
20-24	47	54	[70]	[108]	a
25-29	18	[29]	a	a	a

Note: Duration-specific fertility rates are per 1,000 women. Estimates in brackets are truncated.

^a Less than 125 woman-years of exposure

3.2 Fertility Differentials

Tables 3.4.1 and 3.4.2 present differentials in fertility by residence, region, level of education, and province using the TFR as the measure of current fertility. The first column of each table shows TFRs for the three years prior to the survey (1995 to 1997), the second column presents the percentage of women who are currently pregnant, and the third column presents the mean number of children ever born (CEB) to the oldest women (age 40-49). The mean number of CEB is an indicator of cumulative fertility; it reflects the fertility performance of older women who are nearing the end of their

reproductive period, and thus represents completed fertility. If fertility had remained stable over time, the two fertility measures, TFR and CEB, would be equal or similar.

Table 3.4.1 Fertility: background characteristics

Total fertility rate for the three years preceding the survey, percentage of all women 15-49 currently pregnant, and mean number of children ever born (CEB) to women age 40-49, by selected background characteristics, Indonesia 1997

Background characteristic	Total fertility rate ¹	Percentage currently pregnant ¹	Mean number of CEB to women age 40-49

Total	(2.78)	4.38	4.32

Note: Rates in parentheses indicate that one or more of the component age-specific rates is based on fewer than 250 woman-years of exposure.

¹Women age 15-49 years

In demographic studies of Indonesia, it is important to set the Java-Bali region apart from the rest of the country because of its distinct socioeconomic and political context. In addition to the availability of comparable data from the population censuses and past demographic surveys, family planning programs in this region were initiated earlier than in other regions in the country. Compared with other regions, Java-Bali consistently shows the lowest fertility. However, in recent years, fertility in Outer Java-Bali II has declined rapidly, narrowing the difference in fertility between this region and the rest of the country. At current levels, fertility in Java-Bali is 17 percent lower than in Outer Java-Bali I and 20 percent lower than in Outer Java-Bali II.

As in the 1994 IDHS, the 1997 IDHS findings show an inverted U-shape relationship between education and fertility, where the peak is for women who have some primary education.

Table 3.4.1 also shows that 4 percent of women are currently pregnant. This percentage varies by region, urban-rural residence, and educational attainment, but the differences are not large except by education. The last column of Table 3.4.1 shows that the mean number of CEB among women age 40-49 (4.3) is much higher than the TFR for the three years preceding the survey (2.8), suggesting a substantial reduction in fertility. The same pattern is shown by previous DHS surveys in Indonesia.

Table 3.4.2 shows provincial differentials in fertility. Among the six provinces in Java-Bali, two have reached a fertility level of 2 children or fewer per woman—DI Yogyakarta (1.85) and DKI Jakarta (2.04). The TFR is more than 3 children per woman in all provinces in Outer Java-Bali II except in Jambi, Bengkulu, Central Kalimantan, East Kalimantan, and Southeast Sulawesi.

3.3 Children Ever Born and Living

In the IDHS questionnaire, the total number of children ever born was ascertained by a sequence of questions designed to maximize recall. Since lifetime fertility reflects the accumulation of births over the past 30 years, it has limited direct relevance to the current situation. Nevertheless, the data are important in providing background information for understanding current fertility.

Table 3.5 presents the distribution of all women and of currently married women by the number of children ever born. The table also shows the average number of children ever born and the average number of children still living. Since the respondents in the 1997 IDHS are ever-married women, information on

Table 3.5 Children ever born and living

the reproductive history of never-married women is not available. However, since almost all births in Indonesia occur within marriage, it is safe to assume that never-married women have had no births. Differences in results between all women and currently married women are greatest at the younger ages because of the large proportion of women who are still single and presumed to have had no births.

By the time a woman reaches the end of her childbearing period, she will have given birth to slightly fewer than 5 children. On average, women have less than one child before reaching age 25, close to 3 children by age 35, and more than 4 by their forties.

Voluntary childlessness is rare, and married women with no live births are predominantly those unable to bear children. Survey data imply that primary infertility in Indonesia is low; only 3 percent of married women in their late 30s and 40s have not given birth.

3.4 Birth Intervals

A child's health status is closely related to the length of the preceding birth interval. Children born after a short birth interval are at greater risk of illness and death than those born after a long interval. Further, the occurrence of closely spaced births gives the mother insufficient time to restore her health, which may limit her ability to take care of her children. The duration of breastfeeding for the older child may be shortened, since the mother must breastfeed the younger child.

Table 3.6.1 shows the percent distribution of births in the five years preceding the survey by length of the previous birth interval. First births have been omitted. Overall, relatively long birth intervals prevail in Indonesia. Half of the births in the five years prior to the survey occurred at least 45 months after the preceding birth, and only 15 percent of births took place within two years of a previous birth.

As shown in previous surveys, the 1997 IDHS indicates that birth intervals vary little according to the child's birth order (except for very high birth orders), sex of prior birth, urban-rural residence, mother's education, and mother's work status. However, there are significant differences in birth intervals by mother's age and by survival status of the preceding child. Younger women have on average shorter birth intervals than older women; the median for women age 15-19 is 21.3 months, while for women age 40-44 it is 54.8 months. For children whose preceding sibling is alive, the median interval between births is 15 months longer than for children whose preceding sibling died (47 months, compared with 32 months).

Table 3.6.1 also indicates that birth intervals vary widely by region. The median birth interval in Java-Bali is one year longer than in other parts of Indonesia (52 months, compared with 39 months in both Outer Java-Bali regions).

Table 3.6.2 shows that median birth intervals vary substantially across provinces, ranging from 31 months in East Timor to 59 months in East Java. The same levels were found in the 1994 IDHS.

3.5 Age at First Birth

Table 3.7 presents the distribution of women by current age and age at first birth. The table indicates that women are delaying having their first child. The distribution is similar to that in the 1994 IDHS and shows that the prevalence of early childbearing has declined over time. While 8 percent of women age 45-49 had their first child before age 15, less than 1 percent of women age 15-19 did so. Again, the percentage of women who had their first child between 15-17 years of age is highest among women age 45-49 (22 percent), and lowest among women age 15-19 years (5 percent). The increase in median age at first birth among Indonesian women can also be observed in the last column of Table 3.7; 20.4 years for women age 45-49 and 21.6 years for women age 30-34.

Table 3.6.1 Birth intervals: background characteristics

Percent distribution of non-first births in the five years preceding the survey by number of months since previous birth, according to demographic and socioeconomic characteristics, Indonesia 1997

Note: The interval for multiple births is the number of months since the preceding pregnancy that ended in a live birth.

Table 3.8.1 presents data on differentials in median age at first birth among women age 25-49 years by selected background characteristics. Results of the 1997 IDHS indicate that there are wide differences in the age at which women have their first child. Overall, the median age at first birth is 20.7 years. Urban women start childbearing two years later than their rural counterparts (22.3 years compared with 20.2 years). Women in Java-Bali have their first birth earlier than women in other regions. A positive relationship between educational level and median age at first birth exists. Women with some secondary or higher education start childbearing four years later than women with less than primary education. This relationship is similar for all age groups but is strongest for women age 25-34.

The median age at first birth varies substantially by province, ranging from 19.5 years in Lampung to 22 years or older in DKI Jakarta, DI Yogyakarta, West Sumatra, North Sulawesi, East Nusa Tenggara, East Timor, and Maluku (see Table 3.8.2). Childbearing begins before age 20 in West Java, Lampung, West Nusa Tenggara, and Bengkulu.

Table 3.7 Age at first birth

Percent distribution of women 15-49 by age at first birth, according to current age, Indonesia 1997

Note: The medians for women age 15-24 could not be determined because half the women have not yet had a birth.

3.6 Adolescent Fertility

The topic of teenage fertility is important because teenage mothers and their children are at increased risk of social and health problems. Births to teenage mothers usually follow an early marriage. Because women who marry at an early age often come from poor families with limited education and low health status, their children are more prone to illness and to higher mortality during childhood than other children.

Note: The medians for women age 15-24 could not be determined because half the women have not yet had a birth.

^a Omitted because less than 50 percent of the women had had a birth by age 25.

Table 3.9.1 presents information on fertility among women age 15-19. Teenagers who have never married are assumed to have had no pregnancies and no births. Overall, 12 percent of women 15-19 have started childbearing; 9 percent have had a child, and 3 percent are currently pregnant with their first child. There are large differentials between subgroups of women by age, residence, region, and educational attainment.

As expected, there is a positive relationship between age and fertility; older women are more likely to have started motherhood. While only 1 percent of 15-year-olds have become mothers and 1 percent are pregnant with their first child, by age 19 one in four women has become a mother and 5 percent are pregnant with their first child.

Table 3.9.1 Teenage pregnancy and motherhood: background characteristics

Total	9.4	2.7	12.2	7,298

There is a substantial difference in fertility among teenagers who live in urban and rural areas. The proportion of teenagers who have started childbearing is almost three times higher in rural areas than in urban areas. This pattern exists in all regions. Among the regions, Java-Bali has the highest proportion of teenagers who have begun childbearing (14 percent), while in Outer Java-Bali it is 10 percent or less.

Women's educational attainment is inversely related to the initiation of childbearing; women with less education are more likely to have begun childbearing at a younger age. While one in five women with primary education or less has become a mother or is expecting her first child, the proportion among women who have secondary or higher education is only 5 percent.

Variation in teenage fertility is also found among provinces within regions. Table 3.9.2 shows that among the provinces in Java-Bali, West Java and East Java have the highest percentage of teenagers who have begun childbearing (16 percent). Interestingly, except for Lampung, this percentage is also highest among the 27 provinces in the country. In Outer Java-Bali I, the highest percentage is in Lampung (17 percent), while the lowest is in West Sumatra (4 percent). In the Outer Java-Bali II region, Jambi shows the highest percentage (14 percent), while Maluku and East Timor have the lowest (6 percent or less).

Table 3.9.2 Teenage pregnancy and motherhood: region and province

Percentage of women 15-19 who are mothers or pregnant with their first child, by region and province, Indonesia 1997

CHAPTER 4

KNOWLEDGE AND EVER USE OF FAMILY PLANNING

4.1 Knowledge of Family Planning Methods and Sources

Knowledge of family planning methods and of places to obtain family planning services is crucial in the decision whether to use a method and which method to use. Presumably, more widespread knowledge of family planning methods will result in greater use of contraceptives.

In the 1997 IDHS, data on knowledge of family planning methods were obtained by first asking the respondent to name the ways that a couple can delay or avoid a pregnancy or birth. If she did not spontaneously mention a particular method, the method was described by the interviewer and she was asked if she recognized the method. Descriptions were included in the questionnaire for eleven methods (pill, IUD, injection, intravag¹, condom, implants, female sterilization, male sterilization, abortion, periodic abstinence, and withdrawal). In addition, other methods mentioned spontaneously by the respondent such as herbs (*jamu*), abdominal massage (*pijat*), and prolonged abstinence were recorded. For each method recognized, the respondent was asked whether she had ever used the method. Finally, for all modern methods recognized, she was asked where a person could obtain the method if she wanted to use it. If the respondent recognized periodic abstinence, she was asked where a person could go to obtain advice about the method if she wanted to use it.

Table 4.1 indicates that knowledge of family planning methods and sources for methods is practically universal among ever-married women as well as among currently married women. The percentage of women who

Table 4.1 Knowledge of contraceptive methods and source for methods

Percentage of ever-married women and currently married women who know specific contraceptive methods and who know a source (for information or services), by specific methods, Indonesia 1997

Contraceptive method	Know method		Know a source ¹	
	Ever-married women	Currently married women	Ever-married women	Currently married women
Any method	96.9	97.2	96.2	96.6
Any modern method	96.6	96.9	96.1	96.5
Pill	93.4	93.9	92.0	92.5

Number of women	28,810	26,886	28,810	26,886
Mean number of methods	6.2	6.2	5.5	5.5

NA = Not applicable

¹For modern methods, source refers to a place where the method or procedure can be obtained.

¹A spermicide placed in the vagina.

know any method is the same among ever-married women and currently married women (97 percent), and virtually all of these women recognize at least one modern method.

The most widely known methods among currently married women are the pill, injection, IUD, and implants—known by 94, 94, 85, and 81 percent of women, respectively. Knowledge of the condom and female sterilization is also high, 66 and 61 percent, respectively. Lesser known contraceptive methods include vaginal methods, e.g., intravag, diaphragm, foam, and jelly (12 percent); abortion (32 percent); and traditional methods, known by two out of five married women.

Figure 4.1 shows that knowledge of contraceptive methods among married women continues to increase. Knowledge of implants and injection increased substantially; the proportion of women who have heard of implants has increased from 68 percent in 1991 to 81 percent in 1997. The corresponding percentages for injection are 88 percent in 1991 and 94 percent in 1997. Although knowledge of the other methods increased during the period 1991-1994, it appears to have plateaued during the period 1994-1997.

Table 4.2.1 presents the percentage of currently married women who know of contraceptive methods and sources of services by several background characteristics. Among married women, knowledge of at least one contraceptive method is slightly lower among younger and older women than among women in their 20s and 30s. This pattern also occurs regarding knowledge of modern contraceptive methods and knowledge of places to obtain a modern method.

There are no significant differences in knowledge of contraceptive methods and their sources between urban and rural women. The percentage of married women who know at least one family planning method is 99 percent in urban areas and 96 percent in rural areas. The same relationship holds for knowledge of a modern method and the place to obtain it.

Table 4.2.1 Knowledge of contraceptive methods and source for methods: background characteristics

Percentage of currently married women who know at least one contraceptive method and at least one modern contraceptive method and who know a source (for information or services), by selected background characteristics, Indonesia 1997

Background characteristic	Know any method	Know a modern method ¹	Know a source for modern method	Number of women
Age

Some secondary +	99.3	99.3	99.2	7,680
Total	97.2	96.9	96.5	26,886

¹Includes pill, IUD, injection, intravag/diaphragm/foam, condom, female sterilization, male sterilization and implants.

There are differences in contraceptive knowledge by education; knowledge is higher as education increases. For example, 91 percent of women with no education have heard of a method. The proportion rises to 97 percent among women with some primary school, and to 99 percent of women with some secondary or higher education. With respect to knowledge of family planning sources, the pattern is similar.

Table 4.2.2 shows that there are only slight differences in contraceptive knowledge among regions. The percentage of married women who have heard of at least one contraceptive method in Java-Bali is 98 percent, followed by Outer Java-Bali I and Outer Java-Bali II (95 percent each).

Women who said that they knew a particular method were also asked where they thought a person could go if they wanted to use the method. The responses to this question are summarized in Table 4.3. For

all modern methods except for female and male sterilization, the most commonly named source is the public health center (*puskesmas*). In the case of female and male sterilization, the government hospital is mentioned as a source by 66 percent or more of women. Women who have heard of periodic abstinence are most likely to cite friends and relatives as the potential source of information on how to use the method.

Table 4.2.2 Knowledge of contraceptive methods and source for methods: region and province

Percentage of currently married women who know at least one contraceptive method and one modern contraceptive method and who know a source (for information or services), by region and province, Indonesia 1997

Region and province	Know any method	Know a modern method ¹	Know a source for modern method	Number of women

Total	97.2	96.9	96.5	26,886

¹ Includes pill, IUD, injection, intravag/diaphragm/foam, condom, female sterilization, male sterilization and implants.

Familiarity with private sources such as private doctors and midwives, private hospitals, and pharmacies is acknowledged by a sizeable proportion of women. Twenty-seven percent of women named pharmacies or drugstores as places to obtain condoms, an increase of 9 percentage points compared to that

in 1994 (18 percent). The proportion of women who mentioned private midwife as a source for contraceptive methods is also high. Private midwife is mentioned as the source for injection (32 percent), IUD (22 percent), implants (19 percent), and pill (19 percent). The figures from the 1994 IDHS were considerably lower—18, 11, 9, and 9 percent for injection, IUD, implants, and pill, respectively.

Table 4.3 Source of supply for contraceptive methods

Percent distribution of ever-married women who know a contraceptive method by source of supply or information they would use if they wanted the method, according to specific methods, Indonesia 1997

4.2 Knowledge of Blue Circle

The self-reliant family planning movement or "KB-Mandiri" was introduced in 1987. This approach is based on the belief that people seek family planning services because of some fundamental motivation to create a better life for their family. The self-reliant family planning concept and campaign encourage family planning participants to take responsibility for their family planning needs, including payment for services and supplies. In order to encourage self-reliance, the government implemented a new service scheme that works through private doctors, midwives, clinics, and dispensaries in encouraging the community to fulfill their needs for family planning. In support of the self-reliance effort, a special information, education, and communication (IEC) campaign utilizing social marketing was developed—the Blue Circle campaign.

The program was initiated in large cities, such as Jakarta, Surabaya, and Bandung, and has gradually been expanded to almost all of the municipalities throughout Indonesia. The private-sector program logo, Blue Circle, is present on the package of contraceptives (e.g., condoms and pills) sold to users. For IEC purposes, the Blue Circle logo is also posted outside the offices of private doctors and midwives, and is widely displayed in other strategic locations such as billboards.

Table 4.4.1 Knowledge of Blue Circle: background characteristics

Percentage of ever-married women who have heard of Blue Circle and of those who have heard of Blue Circle, the percentage who think Blue Circle is a private family planning service, by background characteristics, Indonesia 1997

Background characteristic	Among those who heard of Blue Circle, percentage who think it is:				Total	Don't know if heard of Blue Circle	Number of women
	Heard of Blue Circle	Private family planning service	Other family planning service	Don't know			
Age

Rural	39.6	30.2	3.5	66.4	100.0	12.7	2,534
Education							
No education	20.3	17.0	5.4	77.6	100.0	23.5	3,807
Some primary	38.3	20.8	7.6	71.6	100.0	15.5	7,955
Completed primary	59.5	27.0	8.6	64.4	100.0	10.2	8,958
Some secondary +	83.6	38.5	8.7	52.8	100.0	3.2	8,090
Total	55.2	30.2	8.3	61.5	100.0	11.5	28,810

In order to evaluate the progress of the Blue Circle campaign, respondents were asked whether they had ever heard of Blue Circle and, if so, what it was. Table 4.4.1 shows that 55 percent of ever-married women had heard of Blue Circle. Of these, only 30 percent knew that it was a private family planning service, and 8 percent thought Blue Circle referred to other family planning services. Sixty-two percent of those who had heard of Blue Circle said that they did not know what it was.

There has been a slight improvement in the knowledge of Blue Circle. In 1994, 52 percent of women had heard of Blue Circle; of these, 35 percent knew that Blue Circle was a private family planning

service. Thus, in 3 years the level of knowledge of Blue Circle increased by 3 percentage points, from 52 percent in 1994 to 55 percent in 1997. However, a larger proportion of women who have heard of Blue Circle say they do not know what it represents.

Younger women are more familiar with Blue Circle than older women; while about 60 percent of women under 35 years have heard of Blue Circle, the proportion for older women is 51 percent or less.

Urban women are more likely to have heard of Blue Circle than rural women (77 percent compared with 47 percent). This difference is most probably due to the urban focus of the initial campaign. Blue Circle is known throughout the country, with some regional variations. The percentage of women who have heard of Blue Circle is highest in Java-Bali (58 percent), followed by Outer Java-Bali I (52 percent), and Outer Java-Bali II (47 percent).

Knowledge of Blue Circle increases with women's educational attainment, ranging from 20 percent for women with no education, to 84 percent for women with some secondary education.

Table 4.4.2 presents differentials in the knowledge of Blue Circle by province. Eighty-five percent of women in DKI Jakarta have heard of Blue Circle, followed by DI Yogyakarta (79 percent), and East Kalimantan (77 percent). The order in which the provinces ranked in 1994 is almost the same as that in 1997, except the province of West Java was replaced by North Sulawesi in the fifth place. The provincial ranking is consistent with the development of the Blue Circle campaigns that started in large cities. The lowest level of knowledge of Blue Circle is found in East Timor in Outer Java-Bali II (20 percent). However, more than half of these women know that it is a private family planning service.

4.3 Knowledge of Golden Circle

Golden Circle is an extension of the Blue Circle scheme. While the Blue Circle program was successful in increasing the percentage of clients who acquire family planning services through the private sector, the clients need more varied and complete method choices. The Golden Circle program is intended to provide a wide range of contraceptive choices. In order to evaluate the progress of the Golden Circle campaign, IDHS respondents were asked whether they had ever heard of Golden Circle and, if so, whether they knew what it was.

Table 4.5.1 shows that 11 percent of ever-married women have heard of Golden Circle, although the majority of these women do not know the meaning of Golden Circle (69 percent). The percentage of women who know about Golden Circle increased from 8 percent in 1994 to 11 percent in 1997.

Women age 20 to 35 are more likely to know about Golden Circle than do younger or older women. Golden Circle is more widely known in urban areas than in rural areas (17 percent compared with 9 percent). Women's education is positively associated with knowledge of Golden Circle. For example, only 2 percent of women with no education have heard of Golden Circle, compared with 25 percent of women with some secondary education.

Knowledge of Golden Circle varies slightly by region (Table 4.5.2). Ever-married women in Java-Bali are less likely to have heard of Golden Circle (10 percent) than those in Outer Java-Bali I (14 percent or higher). The highest proportion is in Central Kalimantan (30 percent), followed by South Kalimantan (27 percent), Irian Jaya (25 percent), Bengkulu (22 percent), and Bali (20 percent). On the other hand, the lowest level of knowledge of Golden Circle is in West Java and in Dista Aceh (8 percent each). It is interesting to note that although knowledge about Golden Circle in several provinces is low, a moderate proportion of women who have heard of Golden Circle know that it is a private-sector family planning service (e.g., East Nusa Tenggara, Jambi, and East Timor).

Table 4.4.2 Knowledge of Blue Circle: region and province

Percentage of ever-married women who have heard of Blue Circle and of those who have heard of Blue Circle, the percentage who think Blue Circle is a private family planning service, by region and province, Indonesia 1997

Region and province	Among those who heard of Blue Circle, percentage who think it is:				Total	Don't know if heard of Blue Circle	Number of women
	Heard of Blue Circle	Private family planning service	Other family planning service	Don't know

4.4 Dissemination of Family Planning Information

The objectives of the IEC component of Indonesia's family planning movement include the dissemination of knowledge about family planning in particular and the institutionalization of the "small, happy, and prosperous family" norm in general. IEC activities are conducted through the mass media and through family planning groups and workers. The use of the mass media including newspaper, radio, and television, is integral to the IEC program at both the central and provincial levels. Family planning television programs are shown on both central and regional stations run by the government and the private sector. Family planning information is carried on the radio by government and private stations throughout the country.

Table 4.5.1 Knowledge of Golden Circle: background characteristics

Percentage of ever-married women who have heard of Golden Circle and of those who have heard of Golden Circle, the percentage who think Golden Circle is a private family planning service, by background characteristics, Indonesia 1997

Background characteristic	Among those who heard of Golden Circle, percentage who think it is:				Total	Don't know if heard of Golden Circle	Number of women
	Heard of Golden Circle	Private family planning service	Other family planning service	Don't know

Completed primary	8.8	20.4	3.3	76.3	100.0	24.0	8,958
Some secondary+	24.6	32.9	2.8	64.3	100.0	15.9	8,090
Total	11.2	27.3	3.4	69.3	100.0	22.7	28,810

IEC activities are also carried out through community groups that are formed at the village or neighborhood level. IEC activities at periodic community group meetings are generally handled by a family planning fieldworker or by the group leader. Family planning information is also disseminated through word of mouth among neighbors and friends (*gethok tular*).

Family planning workers are defined as those at the grassroots level, including family planning fieldworker supervisors, family planning fieldworkers, cadres, heads and members of village family planning posts, and heads and members of subvillage family planning posts. These people play a very important role in the IEC component of the family planning movement.

Table 4.6.1 shows the percentage of currently married women who were visited by family planning workers in the 6 months prior to the survey. Overall, 25 percent of married women were visited by family planning workers, down slightly since 1994 (28 percent).

Table 4.5.2 Knowledge of Golden Circle: region and province

Percentage of ever-married women who have heard of Golden Circle and of those who have heard of Golden Circle, the percentage who think Golden Circle is a private family planning service, by region and province, Indonesia 1997

Total	11.2	27.3	3.4	69.3	100.0	22.7	28,810

Contraceptive users are much more likely to be visited than nonusers (35 percent, compared with 12 percent). Women under 40 are more likely to receive a visit from a family planning worker than are those 40 and over. The proportion of women visited by family planning workers does not vary significantly by subgroups of women, except that women with no education have the least chance of being visited by family planning workers (17 percent).

While the proportion of married women who were visited by family planning workers varies only moderately by region (Table 4.6.2), there are larger variations among provinces. In Java-Bali, the percentage ranges from 14 percent in East Java to 42 percent in DI Yogyakarta. In Outer Java-Bali I, the corresponding percentages are 11 percent in North Sumatra and 44 percent in West Nusa Tenggara. In Outer Java-Bali II, the lowest percentage is in Jambi (16 percent), and the highest is in Central Kalimantan (49 percent).

Table 4.6.1 Visits by family planning fieldworkers: background characteristics

Percentage of currently married women who have been visited by a family planning fieldworker in the six months prior to the survey, by whether using contraception and selected background characteristics, Indonesia 1997

Background characteristic	Using contraception		Total	Number of women

4.5 Sources of Family Planning Information

Mass media programs used to disseminate information about family planning in Indonesia through radio and television include spot shows, dramas, reports, discussions, and regular series. Another important means of disseminating family planning information is the family planning worker system, which operates in all parts of the country. Family planning workers focus their efforts on motivating family planning use, providing family planning information and recording service statistics. An important aspect of a family planning worker's job is institutionalization, i.e., working with the community and organizations such as mother's clubs, religious groups, women's organizations (PKK), and the organization for wives of civil servants (*Dharma Wanita*). Income-generating activities and rewards to long-term users are among the strategies used to introduce family planning and to maintain motivation. In an effort to investigate which sources of family planning information are reaching ever-married women in Indonesia, the 1997 IDHS included a set of questions on this subject (see Table 4.7.1).

Table 4.6.2 Visits by family planning fieldworkers: region and province

Percentage of currently married women who have been visited by a family planning fieldworker in the six months prior to the survey, by whether using contraception and region and province, Indonesia 1997

Region and province	Using contraception		Total	Number of women

Central Sulawesi	61.3	10.4	36.7	251
Southeast Sulawesi	59.2	11.5	36.9	168
Maluku	50.5	10.9	26.8	220
Irian Jaya	27.3	16.6	22.0	233
Total	34.9	11.7	25.0	26,886

More than half (57 percent) of ever-married women have never received any family planning information from either the radio or television during the month before the survey. Of the 43 percent who have received any information on family planning through the mass media, television messages reach more women (38 percent) than radio messages (23 percent); 19 percent of women have received information on family planning from both the radio and television.

Ever-married women who live in rural areas are more likely not to have access to information on family planning through the mass media than those living in urban areas (61 compared with 49 percent). The percentage of women who have access to family planning information through the television is 50 percent in urban areas, compared with 34 percent in rural areas.

Women with lower education tend to lack access to family planning information in the mass media, compared with better educated women. Likewise, women with higher education tend to receive more information from the television than do women with less education.

Table 4.7.1 Heard family planning on radio and television: background characteristics

Percent distribution of ever-married women by whether they heard a radio or television message about family planning in the month prior to interview, according to selected background characteristics, Indonesia 1997

Background characteristic	Heard a radio or television message about family planning				Total	Number of women
	Neither	Radio only	Television only	Both

Urban	42.2	2.2	29.4	26.0	100.0	686
Rural	56.6	9.5	15.3	18.7	100.0	2,534
Education						
No education	73.4	4.7	10.8	11.1	100.0	3,807
Some primary	64.1	4.5	16.0	15.4	100.0	7,955
Completed primary	56.0	4.8	19.6	19.5	100.0	8,958
Some secondary +	44.9	2.8	27.8	24.5	100.0	8,090
Total	57.4	4.1	19.7	18.7	100.0	28,810

Table 4.7.2 presents the percent distribution of ever-married women according to source of family planning information through electronic media, by province. Provinces with high proportions of women who receive family planning information through radio and television include North Sulawesi, Jambi, Central Kalimantan, Lampung, West Java, and South Sumatra. Women in North Sulawesi and West Java are more likely to receive information about family planning from television (61 and 57 percent, respectively). On the other hand, women in Lampung are most likely to get information on family planning from a radio (52 percent).

Important information for program managers is that large proportions (70 percent or more) of women in certain provinces have no access to family planning information through radio and television. These provinces include East Java, West Kalimantan, East Nusa Tenggara, and East Timor.

Table 4.8.1 indicates that most ever-married women (84 percent) have no access to family planning information through the printed media. The proportion of women who have access to printed materials on family planning is quite low—11 percent through newspapers and magazines, 9 percent through posters, and 5 percent through leaflets and brochures.

Throughout the country, urban women have better access to family planning information through the printed media than women in rural areas. Education appears to have a positive association with access to family planning information through the printed media. Women with some secondary education are most likely to receive family planning information from the printed media, i.e., newspapers and magazines (25 percent), posters (17 percent), and leaflets and brochures (10 percent).

Table 4.7.2 Heard family planning on radio and television: region and province

Percent distribution of ever-married women by whether they heard a radio or television message about family planning in the month prior to interview, according to region and province, Indonesia 1997

Table 4.8.2 presents the proportions of ever-married women who receive family planning information through the printed media, by province. The majority of women (90 percent or more) have no access to family planning information through the printed media in West Kalimantan (92 percent), East Timor (91 percent), North Sumatra (90 percent), and South Sulawesi (90 percent). On the other hand, provinces with the highest coverage to family planning information through newspapers and magazines are DKI Jakarta (27 percent) and East Kalimantan (22 percent). Posters are most often cited as a source of family planning information by women in East Kalimantan (17 percent), Dista Aceh (16 percent), and DKI Jakarta (16 percent), while leaflets and brochures are seen by 10 percent or more of women in Dista Aceh, Irian Jaya, and Central Kalimantan.

Table 4.9.1 presents data on women's perception regarding appropriate sources of family planning information. Midwives and family planning officers are considered appropriate sources of family planning information by more than eight in ten women, while doctors are considered appropriate by 77 percent of women. Women's groups and village leaders are considered good sources of family planning information by more than half of women, while television and radio are deemed acceptable mass media sources (78 and 66 percent, respectively).

Differences by age are minimal; however, urban women are more likely than rural women to feel sources are appropriate vehicles for disseminating family planning information. This applies for every type of source cited.

Overall, women with higher education are more likely to accept various media as a source for family planning information than are women with less education. At least eight in ten women with some secondary or higher education believe that doctors, midwives, family planning officers, and television are appropriate sources of family planning information. The proportions for less educated women are lower.

Provincial differentials in the proportion of women who believe that a specific source of family planning information is appropriate are shown in Table 4.9.2. In most provinces, midwives are the most popular source of family planning information, followed by family planning workers, television, and doctors. It is interesting to note that in Java-Bali, and especially in the province of DI Yogyakarta, a relatively large proportion of women believe that community and village religious leaders are appropriate sources of family planning information.

4.6 Discussion on Family Planning With Husband

In the 1997 IDHS, nonsterilized currently married women were asked if they had ever discussed family planning with their spouses during the year before the survey. Table 4.10 shows that 65 percent of respondents discussed family planning with their husbands, and 35 percent never did. Women age 20-29 are more likely to discuss family planning with their spouses than are older women age 40-49 (74 percent or more, compared with 54 percent or less).

4.7 Ever Use of Family Planning Methods

Information on the proportion of women who have ever used family planning methods is useful for evaluating programs. In the 1997 IDHS, for each method recognized, the respondent was asked if she had ever used that method. Table 4.11 indicates that 76 percent of ever-married women, and 78 percent of currently married women have used or are using any method. The percentage of ever users of any method in 1997 increased slightly, compared with that in 1994 (73 percent for ever-married women, and 76 percent for currently married women).

Among ever-married women, the most common method ever used is the pill (43 percent), followed by injection (42 percent). The next two most common methods are the IUD (18 percent) and implants (9 percent). Much smaller proportions of women report having used the condom (4 percent) and female sterilization (3 percent), as well as traditional methods: periodic abstinence (3 percent), withdrawal (3 percent), and herbs (3 percent). The pattern is similar for currently married women.

Table 4.12 shows the distribution of ever-married women according to the number of living children when they first used family planning. The table is used primarily to identify the acceptance of the small family norm and the use of family planning as a method for spacing births. Data in Table 4.12 show that 43 percent of ever-married women started using family planning before they had two children. Thirty-seven percent of women used family planning for the first time when they had one child, and 15 percent used it when they had two children. Younger women tend to start using family planning when they have fewer

children. While less than 1 percent of women age 45-49 years used contraception when they did not have any children, the corresponding proportion of women age 20-24 and 15-19 was 14 percent and 21 percent, respectively. More than half of women 20-29 started using family planning when they had one child.

CHAPTER 5

CURRENT USE OF FAMILY PLANNING

Information on the current level of contraceptive use (or contraceptive prevalence) is important for measuring the success of the National Family Planning Movement. Contraceptive prevalence is defined as the proportion of currently married women age 15-49 who were using some method of family planning at the time of the survey. This chapter presents data concerning levels, trends, and differentials in current use; sources of family planning methods; age at time of first contraceptive use; accessibility; reasons for using a particular method; and some indicators of the quality of use of the pill, injection, and condom.

5.1 Current Use of Family Planning

Table 5.1 shows that 57 percent of currently married women are using contraception; 55 percent use modern methods, and 3 percent use traditional methods. The prevalence of modern contraceptive use has increased by almost 3 percentage points since 1994. The 1997 contraceptive mix is slightly different from that of 1994. The most commonly used contraceptives in 1997 were injection (21 percent), the pill (15 percent), IUD (8 percent), implants (6 percent), and female sterilization (3 percent), while in 1994 they were the pill (17 percent), injection (15 percent), IUD (10 percent), implants (5 percent), and female sterilization (3 percent). Thus, injectables have replaced the pill as the most commonly used contraception.

Table 5.1 Current use of contraception

Percent distribution of ever-married women and of currently married women by contraceptive method currently used, according to age, Indonesia 1997

¹ Total includes 5 users of intravag/diaphragm/foam.

Modern methods are popular among women of all ages. However, younger and older women are less likely to be using contraception than women in the mid-childbearing ages (20 to 39 years). Injection, the pill, and implants are more common among younger women, whereas long-term methods such as the IUD, female sterilization, and male sterilization are more commonly used by older women.

Use of family planning is slightly higher among urban women than rural women (see Table 5.2.1 and Figure 5.1). Sixty percent of currently married urban women are using a method, compared with 57 percent of rural women. The mix of methods also differs, with urban women relying more heavily on use of the IUD, female sterilization, and traditional methods. Implants, however, are more commonly used by rural women.

Contraceptive use increases with the respondent's level of education. Forty-four percent of currently married women with no education are using a method, compared with 62 percent of women with secondary or higher education. The type of contraceptive being used also varies by the women's level of education. While IUD, injection, and female sterilization are more commonly used by women who have secondary education or higher, women with no education are more likely to use implants and male sterilization.

Figure 5.1
Percentage of Currently Married Women Age 15-49
Who Are Using a Contraceptive Method

IDHS97

Contraceptive use increases rapidly with the number of living children a woman has. It reaches a peak of 69 percent for women with two children, and declines for women with four or more children. Nine percent of childless women are using a method of family planning, mostly the pill, presumably to delay their first birth. After having one child, women tend to use injection, the pill, and implants. Use of female sterilization increases with the number of living children.

Table 5.2.2 shows the proportion of married women who are using contraception by province in each of the three regions. Contraceptive use is highest in Java-Bali (61 percent), followed by Outer Java-Bali I (52 percent), and Outer Java-Bali II (51 percent). In the region of Java-Bali, DI Yogyakarta has the highest prevalence rate (73 percent), followed by Bali (68 percent). Within Outer Java-Bali I, contraceptive use is highest in North Sulawesi (71 percent) and lowest in Dista Aceh (37 percent). The highest level of contraceptive use in Outer Java-Bali II is in Bengkulu (67 percent), and the lowest is in East Timor (27 percent).

There are major differentials in the use of modern contraception within regions. In Java-Bali, modern contraceptive use ranges from 66 percent in Bali to 54 percent in DKI Jakarta. In Outer Java-Bali I, use of modern methods is highest in Lampung (65 percent) and lowest in Dista Aceh (36 percent). The highest level of modern contraceptive use in Outer Java-Bali II is in Bengkulu (62 percent), and the lowest is in East Timor (25 percent).

5.2 Trends in Contraceptive Use

The dramatic changes that have taken place in the level and pattern of contraceptive use in Indonesia over the past 20 years are demonstrated in Tables 5.3 to 5.5. Table 5.3 and Figure 5.2 focus on the provinces that comprise the Java-Bali region, for which it is possible to construct comparable estimates of contraceptive prevalence over the 21-year period from 1976 to 1997. Overall, prevalence doubled in Java-

¹ Total includes 5 users of intravag/diaphragm/foam.

Bali between 1976 and 1994 from 26 percent to 51 percent. However, from 1987 to 1991, the percentage of married women using family planning in Java-Bali increased only slightly (from 51 to 53 percent); between 1991 and 1994, the rate increased from 53 to 58 percent, and between 1994 and 1997 the rate increased from 58 percent to 61 percent. The largest increase in Java-Bali between 1994 and 1997 occurred in East Java (5 percentage points). Contraceptive prevalence has remained at the same level as in 1994 in Bali but has declined slightly in DKI Jakarta.

Table 5.4 and Figure 5.3 show trends in use of specific methods in Java-Bali. Figure 5.3 shows findings from the 1976 IFS, 1987 NICPS and 1997 IDHS. Injection use has increased considerably, especially during the 1994-1997 period when it increased from 17 percent to 24 percent. The use of female sterilization and implants increased somewhat, but has recently hit a plateau, while the use of the pill decreased from 17 percent to 14 percent and the use of IUD from 12 percent to 10 percent. Use of the condom and male sterilization remained limited (under 1 percent). The most significant increase is in the prevalence of the implants, from less than half a percent in 1987 to 3 percent in 1991 and 6 percent in 1997.

Figure 5.2
Percentage of Currently Married Women Age 15-49
Using Contraception, by Province, Java-Bali 1976-1997

IDHS97

Table 5.5 and Figure 5.4 show the percentage of married women in Indonesia using contraception in the 1991, 1994, and 1997 surveys. The overall prevalence was 50 percent in 1991, 55 percent in 1994, and 57 percent in 1997. The use of injection increased rapidly from 12 percent in 1991 to 21 percent in 1997. On the other hand, the use of IUD decreased from 13 percent in 1991 to 10 percent in 1994, and to 8 percent in 1997. While the use of female sterilization has remained constant, the use of the pill, condom, and male sterilization appears to have increased during the period of 1991-1994, but to have decreased during the period 1994-1997.

Table 5.4 Trends in use of specific contraceptive methods: Java-Bali, 1976-1997

Percentage of currently married women who are currently using a specific contraceptive method, by method, Java-Bali, 1976-1997

Method	IFS 1976	NICPS 1987	IDHS 1991	IDHS 1994	IDHS 1997

Figure 5.3
Percentage of Currently Married Women Age 15-49
Using Specific Modern Contraceptive Methods
Java-Bali, 1976-1997

5.3 Contraceptive Use Among Women Over 30 and Among Those With Three or More Children

One of the principles of the family planning movement is that women over 30 and those with three or more children should be using the most effective means of fertility control available. Table 5.6 presents information which can be used to evaluate the success of the program in meeting these goals. In Table 5.6, long-term methods include female and male sterilization, IUD, and implants.

Table 5.5 Trends in use of specific contraceptive methods: Indonesia, 1991-1997

Percentage of currently married women who are currently using a specific contraceptive method, by method, Indonesia 1991-1997

Method	IDHS 1991	IDHS 1994	IDHS 1997
Any method	49.7	54.7	57.4
Pill	14.8	17.1	15.4
IUD	13.3	10.3	8.1
Injection	11.7	15.2	21.1
Condom	0.8	0.9	0.7
Implants	3.1	4.9	6.0
Female sterilization	2.7	3.1	3.0
Male sterilization	0.6	0.7	0.4
Periodic abstinence	1.1	1.1	1.1
Withdrawal	0.7	0.8	0.8
Other	0.9	0.8	0.8
Number of women	21,109	26,186	26,886

Table 5.6 shows that 24 percent of married women have never used a modern contraception, 21 percent used modern methods in the past, and 55 percent are currently using modern contraceptives. About 48 percent of all women age 20-24 years and 47 percent of those age 25-29 are using long-term methods. Long-term methods are also used by 42 percent of women age 30-34. Thus, long-term contraceptives are being used by both younger and older women, regardless of the number of children they have. The use of long-term methods among younger women with one or two children is higher than that recorded in 1994. Temporary methods are commonly used by women age 30 or higher with three or more children.

Figure 5.4
Percentage of Currently Married Women
Age 15-49 Using Specific Contraceptive Methods,
Indonesia, 1994 and 1997

5.4 Reasons for Choice of Contraceptive Method

The reasons women give for choosing their current contraceptive method are important for the family planning movement, particularly in view of the current emphasis on a program of self-sustainability. As shown in Table 5.7, side effects of other methods (27 percent), convenience (22 percent), and the desire for a more effective method (18 percent), are the most common reasons given for having chosen a specific method.

Table 5.6 Contraceptive use status and type of method used

Percent distribution of currently married women by contraceptive use status, and among current users of modern methods, the type of method used (temporary or long-term) by number of living children, according to current age, Indonesia 1997

Current age	Percentage who never used modern method	Percentage who used modern method in the past	Percentage who are currently using a modern method by number of living children						Total	Number of women

Number	4,153	2,191	5,687	179	1,601	826	102	14,736

Note: Total includes some users of other methods not shown separately.

As might be expected, reasons for using a specific method vary according to the method. The majority (53 percent) of condom users stated that they chose the method because it had fewer side effects than other methods. This reason is also commonly stated by pill and injection users (36 and 28 percent,

respectively). Among IUD and injection users, 18 percent and 23 percent, respectively, chose their method because it was considered more effective than other methods, while 28 percent of implants and injection users said that convenience was the main reason for choosing their method.

Substantial proportions of pill users (11 percent) and implants users (7 percent) said they chose their method because it was affordable—a large proportion of implants users receive their method free of charge (see Table 5.13). One in three sterilized women (35 percent) said that they chose this method because they wanted a permanent method, while 19 percent stated that they wanted a more effective method.

5.5 Quality of Use of Pill, Injection, and Condoms

Since the pill is one of the most popular methods of contraception in Indonesia, it is important for program managers to find out whether the method is used properly. For that purpose, the 1997 IDHS included a series of questions on the availability of a pill package in the house at the time of the survey, the brand name, and when the user last took a pill.

Table 5.8.1 indicates that 91 percent of pills users were able to show a package to the interviewer, 85 percent had the pills taken in order, and 83 percent of pill users said they had taken a pill in the 2 days preceding the interview. This means that about 17 percent of pill users are not fully protected from the risks of pregnancy. Table 5.8.1 also shows that there are no significant differences in the quality of pill use according to selected characteristics, except by age. There is a negative relationship between the quality of pill use and age; older women are less likely to have take a pill in the last 2 days than younger women.

The variability of pill compliance among regions and provinces is shown in Table 5.8.2. Provinces in which small proportions of respondents were able to show pill packages are Central Java (81 percent), and Irian Jaya (82 percent). Provinces with the highest percentages (95 percent or higher) include South Kalimantan, Bali, Lampung, Jambi, and DKI Jakarta. The proportion of women who took a pill in the prior 2 days is highest in Dista Aceh (89 percent).

All pill users were asked about the brand of pill they used. Table 5.9 shows that the most popular brand of pill is Nordette 28 (23 percent), Microgynon-Schering (16 percent), and Microgynon 30 ED (11 percent). Other brands that have a sizable number of users are Microgynon Kimia Farma (9 percent), Marvelon 28 (8 percent), Exluton (7 percent), and Blue Circle Microgynon (7 percent). Many other brands were reported, but each was reported by very few women and hence were grouped together.

Table 5.9 also shows condom brands used by respondents. Two brands were used widely. They are BKKBN (21 percent) and Dua Lima (20 percent). Other brands were also mentioned by respondents, but each was used by too few women to be presented separately.

In addition to the quality of pill and condom uses, the 1997 IDHS also investigated the quality of injection use. Interviewers asked all injection users the date of their last injection. Table 5.10 shows that 99 percent of injection users received an injection less than three months before the survey. This means that only one percent of injection users may actually be at risk of pregnancy. The variability in the quality of injection use by background characteristics, region, and province are very small.

5.6 Problems With Current Method

All contraceptive users in the 1997 IDHS were asked whether they had experienced any health problems or any other problems with the method they were using. Table 5.11 shows that the vast majority of contraceptive users did not have any health- or nonhealth-related problems in using the methods.

Table 5.8.1 Pill use compliance: background characteristics

Percentage of currently married women using the pill, and the percentage of pill users who could show pill packet, who took pills in order, and who took a pill less than two days ago, by background characteristics, Indonesia 1997

Education					
No education	12.1	90.0	85.9	83.7	415
Some primary	15.4	89.5	83.2	79.8	1,119
Completed primary	17.7	91.3	84.3	83.9	1,498
Some secondary +	14.5	92.7	85.8	83.0	1,120
Total	15.4	91.1	84.5	82.5	4,153

The proportion of users who experienced health problems is slightly higher among users of hormonal methods than among users of other methods. This is shown by the lower percentages who reported no health problems among injection users (78 percent) and implants users (82 percent). The most common health problem among users of injection and implants is lack of menstruation, while for women who use the pill, the most common problem is headaches.

5.7 Cost and Accessibility of Methods

The Indonesian national family planning movement is implemented by the government with active involvement and participation of the community and private sectors. One of the indicators of community participation in the program is self-sustainability, measured by the proportion of users who pay for the methods and services. All women who used contraceptives were asked where they obtained the method the last time and how much was they paid for it (i.e., the cost for the method and for services).

Table 5.8.2 Pill use compliance: region and province

Percentage of currently married women using the pill, and the percentage of pill users who could show pill packet who took pills in order, and who took a pill less than two days ago, by region and province, Indonesia 1997

Note: Figures in parentheses are based on 25-49 unweighted cases. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.

Table 5.12 shows that 43 percent of users obtained services from a government outlet, and most of them (32 percent) paid for the services and methods. Forty-two percent of users obtained their services from the private sector; almost all of these paid for their method and services. Fifteen percent of users obtained the method and services from other sources such as village birth delivery posts (polindes), integrated health posts (posyandu), family planning posts, village contraceptive distribution centers (VCDC), traditional birth attendants, and friends. The majority of these users also paid for family planning methods and services.

Table 5.9 Use of pill and condom brands

Percent distribution of currently married pill users and condom users by pill/condom brand used, Indonesia 1997

Pill/condom brand	Percent	Number of users
Pill		
Microgynon 30 ED	11.1	458
Microgynon 50 ED	2.1	86

Brand of condom		
BKKBN	20.7	37
Dua Lima	20.4	37
Other	48.9	78
Don't know	*	27
Total	100.0	179

Note: Figures in parentheses are based on 25-49 unweighted cases. An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.

In total, 84 percent of users pay for their contraceptives, and only 16 percent receive free services. Injection users are the most likely to pay for their contraception (97 percent), with pill users close behind (92 percent). Self-sustainability is much lower for the IUD, with only 53 percent of users paying for their method. The level of self-sustainability in 1997 is slightly higher than that in 1994.

As expected, the level of self-sustainability is lowest in Outer Java-Bali II (78 percent), whereas in Java-Bali and Outer Java-Bali I the level is 85 percent and 84 percent, respectively. Among the provinces in Java-Bali, the highest level of self-sustainability is in DKI Jakarta (90 percent), followed by West Java (89 percent), and Bali (88 percent).

Table 5.13 shows the percentage of current users using specific types of sources who get their methods free, and the mean cost of the methods for those who pay. Overall, the 1997 IDHS shows that although those who rely on government sources are much more likely to get free services (26 percent) than those who use private sources (5 percent), those who pay for their methods pay more at a government source than at a private source (Rp.21,216 compared with Rp. 19,813). This pattern differs from that

observed in the 1994 IDHS, in which contraceptive users who obtained their method from a government source paid, on average, half the cost of the same method obtained from a private sector source. Excluding costs for female sterilization, contraceptive users who obtained the method from a private source actually paid, on average, two and a half times more than those who obtained the method from a government source. On average, all contraceptive methods obtained from a government source are cheaper than those obtained from a private source.

The difference in the mean cost varies by method and source of services. By method, the cost of female sterilization is highest both in government or private sources; the cost of the pill is lowest. IUD users who obtain their method from a government source pay much less than those who obtain the method from a private source (Rp.6,345 compared with Rp. 37,328). The cost of injection is almost the same between government and private source, around Rp. 4,000. However, the cost of implants from a private source is almost twice as much as that from a government source (Rp. 13,175 compared with Rp.7,148).

5.8 Source of Method

Information concerning sources of contraceptives is important for family planning program administrators since the family planning movement is currently directed toward self-sustainability and greater use of the private sector. Table 5.14 shows users rely almost equally on government sources (43 percent) and medical private sources (42 percent). Fifteen percent of users obtained their methods from other

Table 5.10 Use of injection

Percentage of currently married women using injection, and the percentage of injection users who received an injection in the last three months, by background characteristics, Indonesia 1997

sources such as *posyandu*, *polindes*, and VCDC. As shown in Figure 5.5, use of government sources decreased from 49 percent in 1994 to 43 percent in 1997, while use of medical private sources increased from 28 to 42 percent, and use of other sources decreased from 23 to 15 percent. The substantial increase in use of private sources is mainly due to the increased use of private midwives (12 percentage points).

Figure 5.6 shows that most of the women who obtain their family planning method through the government sector, obtained it from health centers (31 percent). Among private sources, private midwives are the most popular (28 percent), and among other sources, *posyandu* is the primary choice for family planning services (7 percent).

Table 5.11 Problems with current method of contraception

Percent distribution of current users of modern contraceptive methods by the main health problem with the method and by other nonhealth problem with the method, according to specific methods, Indonesia 1997

Main problem with current method	Method						Female sterilization	Male sterilization

Number	4,153	2,191	5,687	179	1,601	826	102	

Note: Total includes some users of other methods not shown separately.

The source of family planning varies by method. The majority of sterilized women had the operation in a government hospital. Public health centers provide half of implants and IUD insertions. Pill users, on the other hand, obtain their pills from health centers (24 percent), private midwives (19 percent), and integrated health posts (16 percent).

Private sources play a significant role in providing certain methods, especially injection and condom. One out of two users of injection obtain it from a private midwife, while 70 percent of condom users get their supply from a pharmacy or a drugstore.

As part of the family planning movement strategy, programs continue to be developed in enhancing the accessibility and availability of family planning services in order to reach the remote areas, and to provide users with better quality services. However, people select the place where they get family planning services for various reasons. The place selected may be more convenient or give better or cheaper services. In the 1997 IDHS, data on satisfaction with source of supply were obtained by asking current users to mention the main reason they went to the place rather than to some other sources. Table 5.15.1 and Figure 5.7 show that more than half (56 percent) of current users selected the source of supply because of its proximity to their home. Other reasons commonly cited are affordability (9 percent), availability of transportation (6 percent), competency of staff (5 percent), and use other services at the same facility (4 percent).

Table 5.12 Payment for contraceptive methods and services

Percent distribution of current users of modern contraceptive methods by source of method and whether method is free or respondent pays for it, according to method and region, Indonesia 1997

Total	11.0	31.6	2.3	39.8	2.6	12.6	100.0	14,634

Note: Total includes 5 users of intravag/diaphragm/foam.

There is little difference in the selection of the source of supply between current users in urban and rural areas. The main reason for selecting a family planning source varies slightly by province (Table 5.15.2). Proximity to home is the most common reason cited by women in every province but is more pronounced among women in West Kalimantan (69 percent). Availability of transportation (16 percent) and privacy (10 percent) are more frequently cited by women in East Timor. Women in North Sulawesi are more likely than women in other provinces to base their decision on competency and friendly services (15 percent), while women in East Kalimantan cited the use of other services at the same facility (12 percent) more often than other women. However, reasonable cost (33 percent) is the commonly cited by women in West Nusa Tenggara.

5.9 Timing of Sterilization

Given the importance of female sterilization as a way of preventing women in high risk groups to become pregnant, the family planning movement provides information concerning this method. The program also provides services in accordance to the woman's age and health status. Therefore, it is identified as voluntary sterilization. It is of interest to know the trend in the level of use of the method, especially in relation to the age of the woman at the time of operation. In using these data, however, the problem of censoring must be taken into account. Since the survey includes ever-married women 15-49 only, sterilized women age 50 and over are not covered.

Table 5.13 Mean cost of contraceptive methods and services

Percentage of current users of modern contraceptive methods who get their method free and the mean cost (in rupiahs) of the method (including services) for those who pay for it, by type of source, method, region, and province, Indonesia 1997

An asterisk indicates that a figure is based on fewer than 25 unweighted cases and has been suppressed.

¹ The exchange rate is about Rp. 3,700 to US\$ 1.00.

Table 5.16 presents the percent distribution of sterilized women by age at the time of sterilization according to the number of years since the operation. As expected, the vast majority (68 percent) of women were sterilized at age 30 or over. The median age at the time of sterilization is 31.8 years, which suggests no change since 1994 (31.6 years).

Table 5.14 Source of supply for modern contraceptive methods

5.10 Knowledge of the Fertile Period

A basic knowledge of female reproductive physiology and the fertile period is useful for the successful practice of periodic abstinence. The success of periodic abstinence depends on women's understanding of the monthly cycle and the days when a woman is most likely to conceive. Table 5.17 presents information on knowledge of the fertile period among current users of periodic abstinence, current users of calendar rhythm, and current users of any method.

The data indicate that knowledge of the reproductive cycle is generally limited. One in three current users does not know when a woman is most likely to conceive, 32 percent believe a woman can conceive at any time in her cycle, and about 17 percent say that a woman is most likely to conceive just after her period has ended. Only about 16 percent gave the "correct" response that a woman has the greatest chance of conceiving in the middle of her ovulatory cycle.

Figure 5.5
Distribution of Current Users of Modern
Contraceptive Methods by Source of Supply,
Indonesia, 1994 and 1997

Figure 5.6
Distribution of Current Users of Modern
Contraceptive Methods by Source of Supply

IDHS97

Figure 5.7
Distribution of Current Users of Modern
Contraceptive Methods by Reason for Using Most Recent
Source of Supply

IDHS97

Women who are using periodic abstinence are considerably more knowledgeable about the ovulatory cycle than women in general; 68 percent of these women know when they are most fertile, and only 3 percent say they do not know. It should be noted that the precoded response categories for this question are only one way of dividing the cycle into periods. It is possible that women who gave "other" responses, such as "one week after her period," were coded in the category "right after period has ended," instead of in the category "in the middle of the cycle." Thus, women may actually have a more accurate understanding of their cycle than is presented in Table 5.17.

5.11 Knowledge of the Effects of Breastfeeding on Pregnancy

Knowledge of the effects of breastfeeding on pregnancy is very important in the postpartum contraceptive program. Postpartum family planning can be promoted through the use of LAM (lactational amenorrheic method).

Breastfeeding can be an effective method of family planning if the mother has not resumed menstruation after giving birth, and she practices exclusive or near-exclusive breastfeeding within 6 months after the baby is born. In applying the LAM method, if any of the criteria are not met, the woman is at risk of getting pregnant.

Table 5.18.1 presents the distribution of women by knowledge of the effects of breastfeeding on the risk of pregnancy by background characteristics. One in four women said that breastfeeding influences the risk of pregnancy; 17 percent of women said that breastfeeding reduces the risk of pregnancy, 7 percent said it increases the risk of pregnancy, while 28 percent of respondents did not know whether breastfeeding has any impact on the risk of pregnancy. Overall, only 2 percent of women met the LAM method criteria at the time of the survey.

Table 5.15.1 Reason for selecting current sources of supply for contraceptive methods: background characteristics

Percent distribution of current users of modern contraceptive methods by main reason for using current source of supply (rather than another source), according to background characteristics, Indonesia 1997

Background characteristic	Main reason for using current source of supply													Total	Number of users

Number	297	233	15,438

¹ Includes 19 women who use the sympto-thermal method

Women age 25 to 44 years are more knowledgeable about the effect of breastfeeding on the risk of pregnancy than younger or older women. Women in urban areas appear to have more knowledge than those in rural areas (27 percent compared with 12 percent). The knowledge of the effect of breastfeeding on pregnancy is positively associated with education. While 7 percent of women with no education know that breastfeeding can reduce the risk of pregnancy, the proportion for women with secondary or higher education is 30 percent.

On average, knowledge of the effects of breastfeeding on pregnancy varies little between regions, but there are substantial differences among provinces (Table 5.18.2). It appears that the highest level of knowledge of the contraceptive effect of breastfeeding is in DI Yogyakarta (46 percent) followed by DKI Jakarta (41 percent), while the lowest level is in East Nusa Tenggara (4 percent).

CHAPTER 6

FERTILITY PREFERENCES

This chapter addresses questions that allow an assessment of the extent of unwanted fertility in Indonesia, the degree of acceptance of the two-child family norm, and the level of need for contraceptive services. Respondents in the 1997 IDHS were asked questions concerning whether they wanted more children, and if so, how long they would prefer to wait before the next child, and if they could start afresh, how many children in all they would want. Since an underlying objective of the Indonesian family planning program is to persuade couples to have only two children and to space them at least five years apart, it is important to understand to what extent these fertility preferences have been accepted. Two other issues are examined here as well: the extent to which unwanted or mistimed births occur and the effect that the prevention of such births would have on fertility rates.

Interpretation of data on fertility preferences has always been the subject of controversy. Survey questions have been criticized on the grounds that (1) answers are misleading because they may reflect unformed, ephemeral views, that are held with weak intensity and little conviction, and (2) they do not take into account the effect of social pressures or the attitude of other family members, particularly the husband, who may exert a major influence on reproductive decisions.

The first objection has greater force in noncontracepting societies where the idea of conscious reproductive choice may still be alien; preference data from these settings should be interpreted with caution. This objection probably has little relevance in Indonesia where widespread public exposure to the family planning program has no doubt caused most people to establish opinions regarding fertility regulation. The second objection is correct in principle. In practice, however, its importance is doubtful; for instance, the evidence from surveys in which both husbands and wives are interviewed separately suggests that there is little difference in their views.

The inclusion of women who are currently pregnant complicates the measurement of views on future childbearing. For these women the question on desire for more children was rephrased to refer to desire for another child after the one that they were expecting. To take into account the way in which the preference variable is defined for pregnant women, the results have been classified by number of living children, including current pregnancies. In addition, the question on preferred waiting time before the next birth was rephrased for pregnant women to make clear that the information wanted was the preferred waiting time after the birth of the child the respondent was expecting.

Data for women who have been sterilized require special analytic treatment. The general strategy in some tables in this chapter is to classify these women as wanting no more children.

6.1 Desire for Additional Children

Table 6.1 presents the distribution of currently married women by desire for more children, according to the number of living children. Figures in the last column show that 46 percent of these women indicated that they wanted no more children, while 3 percent had been sterilized. Forty-four percent of married women said that they wanted to have additional children; 16 percent wanted the child within two years, 25 percent wanted the child after two years, and 4 percent were unsure about the time. Five percent of women were not sure whether they wanted another child (see Figure 6.1).

Table 6.1 Fertility preferences by number of living children

²Want next birth within 2 years

³Want to delay next birth for 2 or more years

**Figure 6.1
Fertility Preferences of
Currently Married Women 15-49**

*Within 2 years

** After 2 or more years

IDHS97

More than half of currently married women with two children want no more children or have been sterilized. Seven in ten women with three children either have been sterilized or want no more children, and 15 percent want to delay the next birth for at least two years. Findings from the 1994 IDHS show similar patterns, with slightly more desire for terminating childbearing.

Table 6.2 shows the distribution of currently married women by desire for children, according to current age. The table indicates the expected pattern, i.e., younger women (age 15-29) are more likely to want to have another child soon or to space their children, whereas older women (age 30 years and over) tend to want to stop childbearing. For example, 93 percent of women age 15-19 want to have another child, while among women age 30-34 the proportion is 40 percent, and among women age 40-44 it is only 15 percent. At the same time, six in ten women age 15-24 want to delay their next child for at least two years, while at most 19 percent of women 30 years and older want to do so.

Table 6.2 Fertility preferences by age

Percent distribution of currently married women by desire for more children, according to age, Indonesia 1997

¹Want next birth within 2 years

²Want to delay next birth for 2 or more years

Table 6.3.1 shows the percentage of currently married women who want no more children by number of living children and background characteristics. Figures in the bottom row show that the desire to stop childbearing increases significantly among women with two or more children. More than half of women who have two children want no more children, and at least eight in ten women who have four or more children want to stop childbearing.

Looking at differentials by background characteristics, the table shows that in general urban women and women in Java-Bali are more likely to want to terminate childbearing than other women. These differentials were also evident in the 1994 IDHS (CBS et al., 1995). There is an interesting pattern in the data on the proportion wanting no more children by education. At parities one and two, women with less education are more likely to want to stop childbearing than women with more education. At parities four and above, the proportion who want no more children increases with increasing education.

Table 6.3.2 shows the percentage of currently married women who want no more children by region and province. Women in Java-Bali (except West Java) are generally more likely to want to stop childbearing than are women in other regions regardless of the number of children they already have (51 percent, compared with 48 percent or less). The desire to stop childbearing is particularly high in DI Yogyakarta and Bali (more than 60 percent), and low in Dista Aceh and East Timor (36 percent and 27 percent, respectively).

Note: Women who have been sterilized are considered to want no more children.

¹Includes current pregnancy

As observed in the 1991 and 1994 IDHS, Balinese women stand out as having adopted a two-child norm. At least seven in ten women in DI Yogyakarta, East Java and Bali, and North Sulawesi are ready to stop childbearing after having had two children.

6.2 Ideal and Actual Number of Children

Previously, this chapter focused on the respondent's wishes for the future, implicitly taking into account the number of children she already had. In ascertaining the ideal number of children (i.e., ideal family size), the respondent is required to perform the more difficult task of considering, abstractly and independently of her actual family size, the number of children she would choose if she could start again. When asked this question, 21 percent of women in the IDHS gave a non-numeric reply (Table 6.4). The percentage of women who give a non-numeric response increases with the number of children they already have; almost half of women with six or more children were unable to give a numeric response.

Since most ever-married women are currently married, the ideal number of children for both groups is almost the same. Overall, the ideal family size in Indonesia remained the same as in 1994 (2.9 children). Observance of the two-child family norm was slightly stronger in 1997 than in 1994; 37 percent of women reported two children as their ideal family size, compared with 36 percent in 1994. At the same time, the percentage of women whose ideal number of children was three or more declined by 1 percentage point.

Note: Women who have been sterilized are considered to want no more children. Figures in parentheses are based on 25-49 unweighted women.

¹Includes current pregnancy

The correlation between actual and ideal family size can be seen in the fact that women who have a small number of children are more likely to want a small number of children. As parity increases, the ideal number of children also increases. Two reasons have been suggested. First, to the extent that women want to achieve their fertility desires, women who want large families tend to have larger families. Second, women may rationalize their actual family size to be their ideal family size. As the actual number of children increases, their preference increases also. Further, women with larger families—being on average older than women with small families—may have larger ideal family sizes because of attitudes they acquired 20 to 30 years ago.

Despite the likelihood of some rationalization, respondents frequently state ideal family sizes that are lower than their actual number of living children. The difference can be taken as an indicator of surplus or unwanted fertility. At three and higher numbers of surviving children, the proportion of women stating ideal family sizes smaller than their own becomes sizeable. In fact, among women with six or more children, 39 percent say that if they were to start again they would have fewer children.

¹ Includes current pregnancy

Table 6.5.1 presents the mean ideal number of children for all women by age and selected background characteristics. The ideal number of children varies across age groups; older women tend to want larger families than younger women. Urban women and women with some secondary education tend to want smaller families than rural women and women with less education. The mean ideal number of children is negatively associated with woman's education: the higher the level of education, the lower the ideal number of children.

There are notable differences in the mean ideal number of children between regions (see Table 6.5.2). Women in Java-Bali want at least 0.6 fewer children than women in other regions. Variation between provinces is even more substantial, ranging from a low of 2.4 children in DI Yogyakarta, Bali, and North Sulawesi to 4.8 in East Timor. The mean ideal number of children is less than three in all the provinces of Java-Bali, as well as South Kalimantan, North Sulawesi, East Kalimantan, and Central Sulawesi.

6.3 Need For Family Planning Services

Unmet need is defined as the percentage of currently married women who either do not want any more children or want to wait before having their next birth, but are not using any method of family planning. Women with an unmet need for *spacing* include pregnant women whose pregnancy was mistimed, amenorrheic women whose last birth was mistimed, and women who are neither pregnant nor amenorrheic and who are not using any method of family planning and want to wait two or more years for their next birth. Also included in unmet need for spacing are women who are unsure whether they want another child or who want another child but are unsure when to have the birth. Unmet need for *limiting*

refers to pregnant women whose pregnancy was unwanted, amenorrheic women whose last child was unwanted, and women who are neither pregnant nor amenorrheic and who are not using any method of family planning and who want no more children. Measures of unmet need for family planning are used to evaluate the extent to which programs are meeting the demand for services. According to these criteria, in 1997 the total unmet need for family planning services in Indonesia was 9 percent—of which about 5 percent was for limiting and 4 percent for spacing (see Table 6.6.1). A similar pattern was found in 1991 and 1994, when total unmet need was 13 percent and 11 percent, respectively, more or less evenly split between the need for spacing and for limiting.

Note: Figures in parentheses are based on 25 to 49 unweighted women.

Demand for family planning is defined as the sum of contraceptive prevalence (including currently pregnant or amenorrheic women whose pregnancy or last birth was the result of a contraceptive failure) and unmet need (Westoff and Ochoa, 1991). Overall, the total demand for family planning is 67 percent, of which 86 percent has been satisfied. Comparison of the 1994 and 1997 IDHS survey findings indicates that the percentage of the demand that is satisfied has increased by 2 percentage points.

Note: Figures in parentheses are based on 25 to 49 unweighted women; an asterisk indicates that a figure is based on fewer than 25 women and has been suppressed.

Unmet need varies with age. Younger women are more likely to express a need for spacing births, while older women more often want to limit births. There is no notable difference in the need for family planning between urban and rural women. Unmet need generally declines with increasing education; the more educated the women, the lower the percentage with unmet need. Women with no education and women with some primary school are more likely to be in need of family planning for limiting births, whereas more educated women report a greater need for spacing. Additional motivational and service delivery efforts should be directed toward the *limiting* needs of older and less educated women and the *spacing* needs of younger and more educated women.

The total unmet need levels for the Outer Java-Bali regions are slightly higher than for Java-Bali (see Table 6.6.2). The lower unmet need in Java-Bali might reflect the earlier initiation of family planning efforts in that region. Of the 27 provinces, West Sumatra, East Timor, and Maluku have the highest levels of total unmet need (15 percent or higher), while unmet need in DI Yogyakarta, Bali, and North Sulawesi is less than 6 percent.

¹Unmet need for *spacing* includes pregnant women whose pregnancy was mistimed, amenorrheic women whose last birth was mistimed, and women who are neither pregnant nor amenorrheic and who are not using any method of family planning and say they want to wait two or more years for their next birth. Also included in unmet need for spacing are women who are unsure whether they want another child or who want another child but are unsure when to have the birth. Unmet need for *limiting* refers to pregnant women whose pregnancy was unwanted, amenorrheic women whose last child was unwanted and women who are neither pregnant nor amenorrheic and who are not using any method of family planning and who want no more children. Excluded from the unmet need category are pregnant and amenorrheic women who became pregnant while using a method (these women are in need of *better contraception*). Also excluded are menopausal or infertile women.

²Using for *spacing* is defined as women who are using some method of family planning and say they want to have another child or are undecided whether to have another. Using for *limiting* is defined as women who are using and who want no more children. Note that the specific methods used are not taken into account here.

³Total demand includes pregnant or amenorrheic women who became pregnant while using a method (method failure). They account for less than 1 percent of all currently married women.

Within Java-Bali, total unmet need is slightly higher in West Java than in the other provinces; additionally, West Java is the only province in Java-Bali in which total unmet need for family planning (10 percent) exceeds the national average. In the Outer Java-Bali regions, unmet need for limiting and spacing also varies by province. In Southeast Sulawesi and East Timor, for example, most of the unmet need is for spacing births; while in Maluku, on the other hand, the majority of the unmet need is for limiting births.

Table 6.6.2 Need for family planning services: region and province

Percentage of currently married women with unmet need for family planning, and met need for family planning, and the total demand for family planning services, by region and province, Indonesia 1997

¹Unmet need for *spacing* includes pregnant women whose pregnancy was mistimed, amenorrheic women whose last birth was mistimed, and women who are neither pregnant nor amenorrheic and who are not using any method of family planning and say they want to wait two or more years for their next birth. Also included in unmet need for spacing are women who are unsure whether they want another child or who want another child but are unsure when to have the birth. Unmet need for *limiting* refers to pregnant women whose pregnancy was unwanted, amenorrheic women whose last child was unwanted and women who are neither pregnant nor amenorrheic and who are not using any method of family planning and who want no more children. Excluded from the unmet need category are pregnant and amenorrheic women who became pregnant while using a method (these women are in need of *better contraception*). Also excluded are menopausal or infertile women.

²Using for *spacing* is defined as women who are using some method of family planning and say they want to have another child or are undecided whether to have another. Using for *limiting* is defined as women who are using and who want no more children. Note that the specific methods used are not taken into account here.

³Total demand includes pregnant or amenorrheic women who became pregnant while using a method (method failure). They account for less than 1 percent of all currently married women.

Table 6.6.2 indicates that 86 percent of the demand for family planning services has been met. If all of this need were satisfied, a contraceptive prevalence rate of about 67 percent could, theoretically, be expected. DI Yogyakarta, Bali, Lampung, Jambi, Bengkulu, and North Sulawesi lead the other provinces in fulfilling the demand for family planning (90 percent or more), while West Sumatra, East Nusa Tenggara, East Timor, and Maluku lag behind (75 percent or less).

6.4 Unplanned and Unwanted Fertility

In the 1997 IDHS, women were asked a series of questions about each child born in the preceding five years and any current pregnancy, to determine whether the pregnancy was wanted then, wanted but at a later time, or unwanted. These questions form a particularly powerful indicator of the degree to which couples successfully control childbearing. In addition, the data can be used to gauge the effect of the prevention of unwanted births on fertility.

The IDHS questions are extremely demanding. The respondent is required to recall accurately her wishes at one or more points in time during the last five years and to report them honestly. The danger of rationalization is present; an unwanted conception may well have become a cherished child. Despite these potential problems of comprehension, recall and truthfulness, results from previous surveys have proved surprisingly plausible. Respondents clearly are willing to report unwanted conceptions, although some postpartum rationalization probably occurs. The result is more likely an underestimate of unwanted fertility.

Table 6.7 shows the percent distribution of births in the five years preceding the survey and current pregnancies by fertility planning status, according to birth order and mother's age at birth. Eight of ten births were wanted at the time of conception, an additional 9 percent were wanted but at a later time, and only 8 percent were not wanted at all. These findings indicate that women are becoming increasingly successful at planning their families—the proportion of births wanted at the time of conception has increased from 77 percent in 1991 to 82 percent in 1994 and to 83 percent in 1997; the proportion of mistimed births for the corresponding survey years has declined from 16 percent to 10 percent and to 9 percent.

Table 6.7 Fertility planning status					
Percent distribution of births in the five years preceding the survey and current pregnancies, by fertility planning status, according to birth order and mother's age at birth, Indonesia 1997					
Birth order and mother's age at birth	Planning status of birth			Total	Number of births
	Wanted then	Wanted later	Not wanted		
Birth order					
1	94.5	5.0	0.3	100.0	5,896
2	85.2	13.7	1.1	100.0	4,418
3	80.6	9.9	9.5	100.0	2,837
4+	67.9	8.1	24.0	100.0	4,754
Age at birth					
<20	91.1	8.2	0.6	100.0	2,419
20-24	88.9	9.9	1.2	100.0	5,077
25-29	84.5	9.8	5.7	100.0	4,693
30-34	78.3	8.2	13.5	100.0	3,404
35-39	68.3	5.5	26.2	100.0	1,702
40-44	56.0	6.0	37.9	100.0	561
45-49	48.1	8.5	43.4	100.0	50
Total	82.9	8.8	8.3	100.0	17,906
Note: Birth order includes current pregnancy.					

Birth order strongly affects the planning status of births. In the 1997 IDHS, the proportion of births that were wanted at the time of conception decreases with increasing birth order, while the percentage not wanted at all increases. While almost all first births were wanted at the time of conception, one in four of fourth or higher order births were unwanted (see Table 6.7).

The planning status of births is also affected by the age of the mother. In general, the older the mother, the smaller the percentage of children who were wanted at conception. The proportion wanted later increases up to age 20-24 years and then decreases. The percentage of births not wanted increases substantially with age. While almost none of the births to women under 20 years were unwanted, 38 percent or more of births to women age 40-49 were not wanted. This level of unwanted births among older women is higher than that reported in the 1994 IDHS (31 percent or more for women age 40-49).

Tables 6.8.1 and 6.8.2 present *wanted* fertility rates. These are calculated in the same manner as conventional age-specific fertility rates, except that only births classified as *wanted* are included in the numerator. A birth is considered wanted if the number of living children at the time of conception was less than or equal to the current ideal number of children reported by the respondent. Wanted fertility rates express the level of fertility that would theoretically result if all unwanted births were prevented. Comparison of actual fertility rates and wanted fertility rates suggests the potential demographic impact of the elimination of unwanted births.

Overall, the total wanted fertility rate is 14 percent lower than the total fertility rate. Thus, if unwanted births could be eliminated, total fertility in Indonesia would be 2.4 births per woman, instead of 2.8. The differences in wanted fertility rates by various background characteristics are similar to those for actual fertility rates. Wanted fertility rates range from as low as less than 2.0 children per woman in DKI Jakarta, DI Yogyakarta, East Java, and Bali to a high of 4.1 children in East Timor. The wanted fertility rate is 3 or more children in North Sumatra, West Sumatra, East Nusa Tenggara, East Timor, and Irian Jaya.

Note: Rates are based on births to women 15-49 in the period 1-36 months preceding the survey. The total fertility rates are the same as those presented in Table 3.4.2.

CHAPTER 7

NONUSE AND INTENTION TO USE FAMILY PLANNING

This chapter focuses on women who are not using family planning and the reasons women stop using contraceptive methods. Five topics are discussed: contraceptive discontinuation rates, reasons for discontinuing contraception, reasons for nonuse, intention to use contraception in the future, and methods potential users intend to use.

7.1 Discontinuation Rates

Improvement in the quality of contraceptive use is one of the goals of Indonesia's family planning program. One measure of the quality of use is the rate at which users discontinue using a method of contraception. Reasons for discontinuation may include contraceptive failure, dissatisfaction with the method, side effects, and lack of availability. High rates of discontinuation, method failure, and method switching may indicate that improvements are needed in counseling in the selection of methods, follow-up care, and accessibility of services.

Life-table contraceptive discontinuation rates derived from the survey are presented in Table 7.1. These are cumulative first-year discontinuation rates and represent the proportion of users discontinuing a method within 12 months after the start of use. The rates are calculated by dividing the number of discontinuations for each reason at each duration of use in single months by the number of months of exposure at that duration. The single-month rates are then summed to produce a one-year rate. The reasons for discontinuation are treated as competing risks (net rates). Three specific reasons for discontinuation are tabulated: method failure (became pregnant while using contraception), desire to become pregnant, and side effects or health concerns.

Table 7.1 Contraceptive discontinuation rates					
First-year contraceptive discontinuation rates due to method failure, desire to become pregnant, health reasons, or other reasons, according to specific methods, Indonesia 1997					
Contraceptive method	Reason for discontinuation				
	Method failure	To become pregnant	Health/Side effects	All other reasons	All reasons
Pill	4.1	10.4	11.4	7.9	33.9
IUD	1.4	1.4	7.4	2.1	12.3
Injection	1.6	4.2	12.2	5.5	23.5
Implants	0.1	0.1	2.2	0.5	2.9
Condom	6.3	8.4	0.6	22.3	37.7
Periodic Abstinence	12.5	8.9	0.1	7.4	28.8
Withdrawal	11.6	5.1	0.0	14.7	31.4
Total	2.7	5.7	9.8	5.9	24.1

The rates were calculated from information collected in the calendar portion of the 1997 IDHS individual questionnaire. All episodes of contraceptive use between January 1992 and the date of interview were recorded in the calendar along with the reason for any discontinuation of use during this period. The discontinuation rates presented here refer to all episodes of contraceptive use that began during the period covered by the calendar, not all episodes that occurred during this period. Specifically, the first-year contraceptive discontinuation rates presented in Table 7.1 refer to the period 3-63 months prior to the interview; the month of interview and the preceding two months are ignored in order to avoid bias that may be introduced by unrecognized pregnancies.

Overall, 24 percent of contraceptive users discontinued using a method within 12 months of starting use; 3 percent stopped using because they became pregnant while using the contraceptive method (method failure), 6 percent stopped in order to become pregnant, 10 percent cited side effects or were concerned about health problems, and 6 percent stopped for other reasons (including cost, infrequent sex, and availability of method). The highest overall one-year discontinuation rate is for condom users (37 percent), followed by the pill (34 percent), injection (24 percent), and the IUD (12 percent). The rates of discontinuation for traditional methods are 32 percent for withdrawal and 29 percent for periodic abstinence.

The rates of discontinuation according to specific reasons vary by method. For example, the proportion of users who stopped using because they became pregnant (method failure) is highest for users of traditional methods (12 percent or higher) and low for IUD and injection (1 and 2 percent, respectively). Most discontinuation of pill use is due to side effects, health concerns, or the desire to become pregnant. Health concerns and side effects are also the most important reasons given for discontinuing injection use.

Discontinuation rates have declined somewhat since 1994, except for the pill, which remained constant at 34 percent.

7.2 Reasons for Discontinuation of Contraceptive Use

Another perspective on contraceptive discontinuation is provided by Table 7.2, which shows the percent distribution of discontinuations in the five years preceding the survey by reasons for discontinuation, according to method. The most common reason for discontinuing a method is the desire to become pregnant (34 percent). This applies for all methods, except periodic abstinence and withdrawal, for which the most common reason given for discontinuing is method failure. Other reasons for discontinuing a method are side effects (15 percent), health concerns (16 percent), and method failure (11 percent) (see Figure 7.1). Health concerns and side effects are mentioned frequently for implants and injection (17-20 percent), while method failure is a commonly cited reason for discontinuing traditional methods. The reasons for discontinuing contraceptive methods have changed little since 1994.

7.3 Intention To Use Contraception in the Future

Intention to use contraception in the future provides a forecast of potential demand for family planning services and represents a summary indicator of attitudes toward contraception among current nonusers. The distinction between intention to use in the next 12 months and intention to use later is useful in assessing the extent of demand in the near future. In Indonesia, where the contraceptive prevalence rate is high, nonusers are the group most targeted by family planning programs and providers.

Respondents who were not using any method of contraception at the time of the interview were asked if they intended to use a method at any time in the future. Table 7.3 presents the distribution of currently married women who are not using a contraceptive method by intention to use in the future,

according to number of living children. According to the 1997 IDHS data, 41 percent of nonusers intend to use family planning some time in the future, and 46 percent do not intend to use. The remaining women are unsure about their intentions (14 percent). Among women who intend to use, most intend to use contraception in the next 12 months. Intention to use a family planning method is highest among women with one child; however, women with 2 or 3 children are more likely to want to use contraception within the next 12 months. It is interesting to note that 44 percent of women with no children intend to use family planning some time in the future.

Table 7.2 Reasons for discontinuation

Percent distribution of discontinuations of contraceptive methods in the last five years by main reason for discontinuation, according to specific methods, Indonesia 1997

Reason for discontinuation	Method								
	Pill	IUD	Injection	Condom	Implants	Periodic abstinence	Withdrawal	Other methods	All methods
Became pregnant	14.5	12.5	6.8	21.3	0.8	39.3	35.9	29.1	11.4
To become pregnant	37.0	30.4	32.0	21.3	29.4	36.8	29.5	36.1	33.5
Husband disapproved	0.7	0.5	0.3	3.5	0.1	2.0	4.7	1.3	0.6
Side effects	11.7	14.6	19.9	0.2	17.2	0.1	0.4	0.6	15.0

Marital dissolution	2.2	2.0	1.9	4.8	3.5	0.3	1.0	2.9	2.2
IUD expelled	0.2	6.1	0.3	0.0	1.9	0.2	0.0	0.4	0.9
Other	3.0	4.0	3.4	6.5	13.8	0.8	1.3	9.1	3.9
Don't know	0.1	0.2	0.0	0.0	0.1	0.0	0.0	0.6	0.1
Total	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0
Number of discontinuations	4,344	1,114	4,978	147	688	261	180	148	11,884

Note: Total includes 23 discontinuations of intravag/diaphragm/foam and 3 discontinuations of male sterilization.

7.4 Reasons for Nonuse

One of the best ways of assessing obstacles to family planning programs is to ask women why they are not using a contraceptive method; this was done in the 1997 IDHS. Table 7.4 gives the distribution of currently married nonusers who do not intend to use family planning by reason for not using contraception, according to age.

The major reasons for not intending to use a contraceptive method are the desire to have more children (20 percent) and menopause or having had a hysterectomy (19 percent). As expected, the proportion who do not intend to use because they want to have more children is greater among younger than older women (38 percent for women age 15-29, compared with 17 percent for women age 30-49). Overall, 22 percent of nonusers age 30 and over say that they do not intend to use contraception because they are menopausal or have had a hysterectomy.

Fear of side effects and health concerns are the next most commonly cited reasons for nonuse (12 and 11 percent, respectively). Based on this finding, family planning counseling is recommended to eliminate any misunderstandings women may have about methods and to explain more about the possible side effects. This would enable nonusers to make informed choices about the use of contraceptive methods.

Table 7.4 Reasons for not using contraception

Percent distribution of currently married women who are not using a contraceptive method and who do not intend to use in the future, by main reason for not using, according to age, Indonesia 1997

7.5 Preferred Method

Table 7.5 presents data on women who are not currently using family planning but intend to use in the future. An overwhelmingly large proportion of women want to use injection (45 percent), while 26 percent say that they want to use the pill. There is little variation in the potential method choice between women who intend to use in the next 12 months and those who intend to use later.

Comparison of the results of this survey with those of the 1987 NICPS, the 1991 IDHS, and the 1994 IDHS shows that gradually larger proportions of women intend to use injection (from 34 percent in 1987 to 45 percent in 1997), and smaller proportions intend to use the pill (from 40 percent in 1987 to 26 percent in 1997).

CHAPTER 8

OTHER PROXIMATE DETERMINANTS OF FERTILITY

The principal factors, other than contraception, that affect a woman's risk of becoming pregnant—marriage, sexual intercourse, postpartum amenorrhea, postpartum abstinence from sexual relations, and secondary infertility—are discussed in this chapter. Marriage is a primary indicator of exposure to the risk of pregnancy and is, therefore, important for an understanding of fertility. Low age at first marriage is usually associated with early childbearing and high fertility. Trends in the age at which women marry can help explain trends in fertility levels.

This chapter also presents information on more direct measures of the beginning of exposure to pregnancy and of the level of exposure, such as age at first sexual intercourse and the frequency of intercourse. Other factors that influence the risk of pregnancy, including the duration of postpartum amenorrhea, postpartum abstinence, and secondary infertility are discussed.

In the 1997 IDHS, ever-married women age 15-49 were asked about their current marital status, i.e., whether currently married, divorced, or widowed. Some of the tables in this report are based on data from both ever-married and never-married women. Figures that include never-married women are calculated by multiplying the number of interviewed ever-married women by an inflation factor that is the ratio of all women to ever-married women as reported in the household questionnaire. This procedure expands the denominators of the tables to be representative of all women. The inflation factors are calculated by single years of age and, if results are presented by background characteristics, the single-year inflation factors are calculated separately for each category of the background characteristics.

8.1 Current Marital Status

Table 8.1.1 shows the marital status of women at the time of the survey, by age. Overall, one in four women have never been married, and seven in ten are currently married. The proportion of single women has decreased slightly from that reported in the 1991 IDHS and the 1994 IDHS. In the 1997 IDHS, the

Table 8.1.1 Current marital status by age

Percent distribution of the household population of women age 15-49 by current marital status, according to age, Indonesia 1997

Age	Marital status				Total	Number of women
	Never married	Married	Divorced	Widowed		
15-19	82.0	17.1	0.9	0.0	100.0	7,298

Total	25.3	69.7	2.5	2.5	100.0	38,590

Note: Figures may not add to 100.0 due to rounding.

percentage of women who have never married decreases rapidly from 82 percent among teenagers to 36 percent among women age 20-24, while the proportion of divorced women increases gradually with age from 2 percent among women 20-24 to 4 percent among women age 40-44. The proportion of women who are widowed increases steadily with age, from less than 1 percent of women under age 30, to 6 percent of women age 40-44, and then to 13 percent of women age 45-49.

The marital status of women by province is displayed in Table 8.1.2. Among the provinces, the largest proportion of women never married is found in DKI Jakarta (39 percent), while East Java has the lowest proportion (20 percent). On the other hand, the proportion of married women is lowest in DKI Jakarta (55 percent), while the proportion in East Java is highest (74 percent). The percentage of divorced women ranges from less than 1 percent in East Timor to 7 percent in West Nusa Tenggara. DKI Jakarta and East Java also have a high proportion of divorced women—3 percent and 4 percent, respectively. The extent of widowhood also varies across provinces, ranging from 1 percent in North Sulawesi to 4 percent in Dista Aceh, South Kalimantan, and East Nusa Tenggara.

8.2 Age at First Marriage

Table 8.2 shows the percentage of women ever married by selected exact ages and median age at first marriage, according to current age. There is a substantial increase in age at first marriage across cohorts. One in five women age 45-49 was married by age 15, compared with 14 percent of women age 30-34 and with less than 6 percent of women age 20-24. Similarly, while 7 in 10 women age 40 and older were married by age 20, less than half of the women age 20-24 were married by age 20.

Table 8.2 Age at first marriage

Percentage of women who were first married by exact age 15, 18, 20, 22, and 25, and median age at first marriage, according to current age, Indonesia 1997

NA = Not applicable

^a Omitted because less than 50 percent of the women in the age group x to $x + 4$ were first married by age x .

The median age at first marriage is defined as the age by which 50 percent of women in the age group x to $x+4$ have been married. For example, 50 percent of women age 25-29 were married by age 19.9. The median age at first marriage has increased from 17.3 years among women in the oldest age cohort to 19.9 years among those age 25-29. Between 1994 and 1997, the median age at first marriage among women age 25-49 increased from 18.1 to 18.6 years (CBS et al., 1995).

Large differences in age at first marriage according to women's residence and level of education can be seen in Table 8.3.1 For all age cohorts, urban women marry at least two years later than their rural counterparts; this pattern applies throughout the country. A large difference can be found in the younger age group. For urban women age 25-29, the median age at first marriage is 22.7 years, whereas the figure for rural women is 18.9 years. The difference between women with some secondary education and all other women is especially pronounced. Overall, women who have attended secondary school marry at least five years later than women with less than completed primary education. Among women with some secondary education, the median age at first marriage is 22 years, whereas for women with less than primary education the median age at first marriage is 17 years or younger. In general, the gap between women with secondary schooling and other women is larger among younger women.

Table 8.3.1 Median age at first marriage: background characteristics

Median age at first marriage among women age 25-49 years, by current age and selected background characteristics, Indonesia 1997

Background characteristic	Current age					Women age 25-49

Education						
No education	17.4	17.0	17.0	17.2	16.1	16.9
Some primary	17.3	17.4	17.5	17.2	16.7	17.3
Completed primary	18.5	18.0	17.9	17.8	17.4	18.0
Some secondary+	22.7	22.7	21.4	20.9	20.5	22.0
Total	19.9	18.8	18.1	18.1	17.3	18.6

Note: The medians for women 15-19 and 20-24 could not be determined because less than 50 percent of the women were first married by age 15 and 20, respectively.

Women in Java-Bali marry more than one year earlier than women in outer islands. The median age at first marriage is 18.1 years in Java-Bali, compared with 19.2 years in Outer Java-Bali I, and 19.7 years in Outer Java-Bali II (Figure 8.1).

There is a great deal of variation in the median age at first marriage by province (Table 8.3.2). In Java-Bali, the median age at first marriage for women 25-49 ranges from 17.4 years in West Java to almost 20.7 years in DI Yogyakarta (Figure 8.2). While in the Outer Java-Bali regions, the corresponding figure ranges from 17.5 years in Lampung to 21 or older in North Sulawesi, East Nusa Tenggara, East Timor, and Maluku. Since 1987, the median age at first marriage has increased in most provinces. However, a few provinces have shown slight declines from the median recorded in the 1994 IDHS, such as North Sumatra, West Nusa Tenggara, and Central Kalimantan.

8.3 Age at First Sexual Intercourse

IDHS respondents who were currently married were asked at what age they first had sexual intercourse. This information is presented in Table 8.4. In the table, divorced and widowed women are assigned an age at first intercourse equal to that of the last currently married women in the data file who got married at the same age, while never-married women are assumed not to have had sexual intercourse. For Indonesia as a whole, less than 6 percent of women age 25-49 reported never having had sexual intercourse, 15 percent of women had had intercourse by age 15, and by age 18 this figure rises to 44 percent. The patterns shown in this table are almost identical to those for age at first marriage (Table 8.2), indicating that, for most women, first sexual intercourse occurs at the time of first marriage.

Figure 8.1
Median Age at First Marriage by Region
Indonesia, 1991, 1994 and 1997

The differentials in age at first sexual intercourse (see Table 8.5.1) are similar to the differentials in age at first marriage. Rural women, women in Java-Bali, and women with less than secondary education have first sexual intercourse at an earlier age than other women.

In West Java, women age 25-49 have first sexual intercourse at an earlier age (17.4 years) than women in other provinces in the country (Table 8.5.2). Within Outer Java-Bali I, women in Lampung have their first sexual intercourse at an earlier age (17.5 years) than women in the other provinces, and within Outer Java-Bali II, women in Jambi have the lowest median age at first sexual intercourse (18.0 years). East Timor has the highest median age at first sexual intercourse (21.2 years).

8.4 Recent Sexual Activity

In the absence of contraception, the probability of pregnancy is related to the frequency of sexual intercourse. Thus, information on intercourse is important for refining the measurement of exposure to pregnancy. Several questions in the 1997 IDHS covered the topic of recent sexual intercourse. For example, currently married women were asked how long ago they had last had sexual intercourse and how many times they had had sex in the last 4 weeks.

Tables 8.6.1 and 8.6.2 present the results of the question on time since last intercourse. The data allow an assessment of the level of sexual activity according to age, marital duration, and other background characteristics. Overall, 82 percent of married women were sexually active in the month preceding the survey, 4 percent were postpartum abstaining, and 14 percent were not sexually active for reasons other than a recent birth (e.g., spousal separation, illness). The proportion sexually active and the proportion postpartum abstaining declines as age and marital duration increase. At the same time, the proportion not sexually active for other reasons increases with increasing age and duration of marriage.

Table 8.3.2 Median age at first marriage: region and province

Median age at first marriage among women age 25-49 years, by current age and region and province, Indonesia 1997

South Sulawesi	20.9	21.4	19.1	19.0	18.4	19.8
Outer Java-Bali II	20.5	19.7	19.4	18.8	19.5	19.7
Riau	21.2	19.3	18.9	17.9	17.9	19.1
Jambi	18.7	17.4	18.2	17.1	18.3	18.0
Bengkulu	18.9	18.2	17.7	17.4	17.9	18.1
East Nusa Tenggara	22.5	21.5	21.3	20.4	21.0	21.4
East Timor	21.2	20.7	21.0	23.4	24.5	21.5
Central Kalimantan	19.0	18.9	19.0	18.5	19.3	18.9
East Kalimantan	20.8	20.4	18.8	17.7	17.0	19.4
Central Sulawesi	20.1	19.9	20.1	19.3	19.9	19.8
Southeast Sulawesi	19.7	19.4	18.4	18.5	18.9	19.0
Maluku	21.0	20.9	21.0	21.6	22.8	21.2
Irian Jaya	19.9	18.8	18.4	19.0	20.4	19.2
Total	19.9	18.8	18.1	18.1	17.3	18.6

Note: The medians for women 15-19 and 20-24 could not be determined because less than 50 percent of the women were first married by age 15 and 20, respectively.

Urban women are slightly more likely to be sexually active than rural women (Table 8.6.2). Sexual activity in the month preceding the survey is associated with women's education. Women with no education are less likely to be sexually active than educated women, because of the greater proportion of less educated women among those abstaining for reasons other than a recent birth.

Among contraceptive users, the proportion of women who are sexually active varies little according to the method they are using (from 83 to 93 percent). However, women who are not using any method of family planning are less likely to be sexually active than those who are using a method. Among women who

were not using family planning, 74 percent had had sex in the month prior to the survey, 7 percent were postpartum abstaining, and 19 percent were abstaining for other reasons.

Although there are small differences between regions in the proportion of women who were sexually active in the four weeks preceding the survey, there are substantial variations by province. Proportions range from a low of 70 percent in Central Java to a high of 92 percent in Bali and East Timor. The low proportion of women who are sexually active in Central Java corresponds to the high proportion of women who are abstaining for other reasons, such as temporary separation.

8.5 Postpartum Amenorrhea, Abstinence and Insusceptibility

Among women who are not using contraception, exposure to the risk of pregnancy in the period following a birth is influenced by two factors—breastfeeding and sexual abstinence. Postpartum protection from conception can be prolonged by breastfeeding, which can lengthen the duration of amenorrhea, and by delaying the resumption of sexual relations.

Table 8.7 shows the percentage of births for which mothers are postpartum amenorrheic, abstaining, and postpartum insusceptible by the number of months since the birth. Women who are insusceptible are defined as those who are either amenorrheic or abstaining following a birth and, thus, are not exposed to the risk of pregnancy. The estimates shown in Tables 8.7, 8.8.1 and 8.8.2 are based on current status data. That is, they refer to whether or not the woman was amenorrheic or abstaining at the time of the survey. All births occurring during the three years prior to the survey are included. Table 8.7 uses cross-sectional data,

representing all women at a single point in time, rather than showing the experience of an actual cohort over time. For this reason, the proportions at increasing duration do not always decline smoothly. Such fluctuations have been reduced by grouping the births in two-month intervals.

The percentage of women who are still amenorrheic is 64 percent at 2 to 3 months after birth, 48 percent at 6 to 7 months, and 31 percent at 12 to 13 months (Figure 8.3). From the table, it can be seen that there is a rapid drop in postpartum abstinence; while 42 percent of women are still abstaining from sexual relations 2-3 months after a birth, only about 4 percent are abstaining after a year. Overall, half of the women are susceptible to the risk of pregnancy 7-8 months after the birth of a child (excluding contraceptive use).

Table 8.6.1 Recent sexual activity: background characteristics

Percent distribution of currently married women by sexual activity in the four weeks preceding the survey, and among those who were not sexually active, the length of time they had been postpartum abstaining or were abstaining for other reasons, according to selected background characteristics and contraceptive method currently used, Indonesia 1997

The median duration of postpartum amenorrhea, abstinence, and insusceptibility, by various background characteristics of women, are shown in Table 8.8.1. Women less than 30 years of age and urban women are amenorrheic for a shorter period than women over age 30 and rural women, although the period

of abstinence is similar. The duration of amenorrhea in the three major regions varied little, ranging from 5.2 months in the Outer Java-Bali II region to 6.0 months in Java-Bali. Education has an inverse relationship to the duration of amenorrhea. Women with no education are amenorrheic almost three times as long (11.6 months) as women with some secondary education (3.3 months). The difference is largely due to longer breastfeeding among rural and older women (see Chapter 13).

Table 8.6.2 Recent sexual activity: region and province

The combined effect of amenorrhea and abstinence is reflected in the median duration of insusceptibility, which is shown in Table 8.8.1 and Table 8.8.2. Women under 30 years of age are insusceptible to the risk of pregnancy almost 4 months less than women 30 years and over (5.8 months versus 9.5 months); the corresponding periods for urban and rural women are 4.0 and 9.3 months, respectively. Women with less education are insusceptible for a longer period than more educated women (12.2 months for women with no education and 4.4 months for women with some secondary education).

Table 8.7 Postpartum amenorrhea, abstinence and insusceptibility

Percentage of births in the three years preceding the survey for which mothers are postpartum amenorrheic, abstaining and insusceptible, by number of months since birth, and median and mean durations, Indonesia 1997

Total	28.2	11.0	31.1	9,685
Median	5.7	2.4	7.5	NA
Mean	10.4	4.4	11.4	NA
Prevalence/ Incidence mean ¹	10.0	3.9	11.0	NA

NA = Not applicable

¹The prevalence-incidence mean is borrowed from epidemiology and is defined as the number of children whose mothers are amenorrheic (prevalence) divided by the average number of births per month (incidence).

Table 8.8.2 presents the differentials in postpartum amenorrhea by region and province. Postpartum amenorrhea ranges from less than 3 months in DKI Jakarta and Irian Jaya to more than 10 months or longer in Central Java, East Nusa Tenggara, and East Timor.

Differences in the duration of abstinence tend to be less pronounced than those in amenorrhea. In almost all groups, women abstain for 2 to 3 months following a birth. In DI Yogyakarta, East Java, Lampung, and Maluku, the duration of abstinence is somewhat longer—more than 3 months. Regional differences in the duration of insusceptibility generally replicate the differences in the duration of amenorrhea. The median duration of insusceptibility for women in Central Java, East Java, East Nusa Tenggara, and East Timor is 10 or more months, which is caused by the long duration of postpartum amenorrhea, and in East Java by the period of abstinence.

Table 8.8.1 Median duration of postpartum amenorrhea, abstinence, and insusceptibility: background characteristics

For births in the three years preceding the survey, the median number of months mothers are postpartum amenorrheic, postpartum abstaining, and postpartum insusceptible, by selected background characteristics, Indonesia 1997

Note: Medians are based on current status.

8.6 Termination of Exposure

Two measures of exposure—menopause and long-term abstinence—are shown in Table 8.9. Menopause is an indicator of secondary infertility—the proportion of non-pregnant, non-amenorrheic currently married women whose last menstrual period occurred 6 or more months prior to the survey or who report that they are menopausal. This proportion rises rapidly with age, particularly after age 42. The proportion menopausal is 10 percent before age 42 and reaches 48 percent in the oldest age group (age 48-49).

Long-term abstinence is an indicator of terminal abstinence—the percentage of currently married women who did not have sexual intercourse in the three years prior to the survey. Although long-term abstinence is an important factor in the termination of exposure in some countries, especially in sub-Saharan Africa, it is not significant in Indonesia, where only 4 percent of women in the oldest age group are terminally abstaining.

Table 8.8.2 Median duration of postpartum amenorrhea, abstinence, and insusceptibility: region and province

For births in the three years preceding the survey, the median number of months mothers are postpartum amenorrheic, postpartum abstaining, and postpartum insusceptible, by region and province, Indonesia 1997

CHAPTER 9

INFANT AND CHILD MORTALITY

9.1 Background

For some time, Indonesia's health programs have focused on reducing the high levels of infant and childhood mortality. Various efforts have been carried out to achieve the goal of "a healthy population by the year 2000." To reach this goal, the government developed the National Health System, which is part of the national development plan. The infant mortality rate has been identified as one of the key indicators used to assess improvements in health development.

Infant and child mortality rates are relevant not only in evaluating the progress of health programs, but also in monitoring the current demographic situation and providing input for population projections. In addition, they can be used to identify subgroups of the population that have high mortality risks.

This chapter reports on levels, trends, and differentials in infant and child mortality based on the 1997 IDHS and selected earlier surveys. The following rates are used to measure early childhood mortality:

- Neonatal mortality:** the probability of dying within the first month of life;
- Postneonatal mortality:** the probability of dying after the first month of life but before exact age one year;
- Infant mortality:** the probability of dying between birth and exact age one year;
- Child mortality:** the probability of dying between exact age one and exact age five;
- Under-five mortality:** the probability of dying between birth and exact age five.

Data on infant and child mortality in the 1997 IDHS are derived from the birth history section of the individual questionnaire. The section begins with questions about the respondent's childbearing experience, i.e., the number of sons and daughters who live in the household, who live elsewhere, and who have died. Next, for each live birth, information on name, date of birth, sex, whether the birth was single or multiple, and survivorship status was recorded. For living children, information about his/her age at last birthday and whether the child resided with his/her mother was obtained. For children who had died, the respondent was asked to provide the age at death.

9.2 Assessment of Data Quality

A retrospective birth history, such as that included in the 1997 IDHS, is susceptible to several possible data collection errors. First, only surviving women age 15-49 were interviewed; therefore, no data were available for children of women who had died. The resulting mortality estimates will be biased if the fertility of surviving and nonsurviving women differs substantially. In Indonesia, this bias is likely to be negligible. Another possible error is underreporting of events; respondents are likely to forget events that occurred in the past. Also, the misreporting of date of birth and/or age at death can bias rates. In general, these problems are less serious for time periods in the recent past than for those in the more distant past.

The existence and extent of some of these potential biases can be examined with the 1997 IDHS data. As shown in Table C.4 in Appendix C, there is a deficit of births in calendar year 1992 and an excess in calendar year 1991. This pattern, which has been found in previous DHS surveys, is thought to result from interviewers' transference of births out of the period for which the health and calendar data were collected (i.e., January 1992 through the date of the survey) in order to reduce their workload.

The most common source of error in the reporting of children's age at death is the tendency of mothers to report them as occurring at multiples of six months. To reduce this type of error, detailed instructions were given to the interviewers to record age at death under one month in *days*, and age at death under two years in *months*. Interviewers were also instructed to probe for exact age at death in months when it was reported as "one year" or "12 months." Nevertheless, as shown in Figure 9.1, there is considerable heaping of deaths at age 12 months. The same pattern was found in the 1994 IDHS. Heaping in age at death is more severe for deaths that occurred farther in the past than for those that occurred more recently. It should be noted that although misreporting of age at death may result in biased estimates of infant and child mortality, a simulation study using DHS data indicates that the magnitude of misreporting evident in the 1997 IDHS would bias estimates by no more than 5 percent (Sullivan et al., 1990). Thus, the results presented in this report are unadjusted for misreporting. In particular, all deaths reported as occurring at 12 months are not included in the calculation of the infant mortality rate.

It should also be noted that most infant and child mortality estimates using survey data are based on relatively small numbers of cases, particularly when fertility levels are low. This situation can lead to unstable estimates. To reduce this problem, mortality measures based on the 1997 IDHS are calculated for five- or ten-year periods.

Another problem concerns the fact that the mortality estimates are based only on those births reported by women of reproductive age at a given point in time and these are truncated because women past age 49 are not interviewed. As the time period covered extends further into the past, the resulting censoring of information becomes progressively more severe, and the higher rates of infant and child mortality are usually associated with more advanced maternal ages. To minimize the effect of censoring, analysis of infant and child mortality trends from the 1997 IDHS is limited to a period no more than 15 years prior to the survey.

9.3 Levels and Trends in Infant and Child Mortality

Table 9.1 presents estimates of childhood mortality for three five-year periods preceding the survey. The data indicate that infant mortality has declined 30 percent during the fifteen-year period, from 65 deaths per 1,000 live births in the period 1982-1987 to 46 per 1,000 in the period 1992-1997. During the same period, postneonatal mortality, child mortality, and under-five mortality declined at a faster rate (35 percent, 58 percent, and 39 percent, respectively), while the neonatal mortality rate declined by only 23 percent. The direct estimate of infant mortality for the most recent five-year period, 46 deaths per 1,000 births, is consistent with an estimate calculated using an indirect estimation technique referring to the year 1993 (51 deaths per 1,000 births)¹ (CBS, 1997b).

Years preceding survey	Approximate calendar periods	Neonatal mortality (NN)	Post-neonatal mortality (PNN)	Infant mortality (Iq ₀)	Child mortality (4q ₁)	Under-five mortality (5q ₀)	Post-neonatal/neonatal mortality ratio
0-4	1992-1997	21.8	23.9	45.7	13.1	58.2	1.10
5-9	1987-1992	28.2	30.3	58.5	25.6	82.6	1.07
10-14	1982-1987	28.4	37.0	65.4	31.3	94.7	1.30
0-9	1987-1997	25.0	27.2	52.2	19.4	70.6	1.09

Table 9.1 also gives infant mortality rates for the ten-year period preceding the survey. For infant mortality, the rate is 52 deaths per 1,000 live births; the neonatal mortality rate is 25 per 1,000, and the ratio of postneonatal to neonatal mortality is 1.09. For the same time period, the probability of dying between birth and the fifth birthday was 71 per 1,000 live births. The data indicate that the under-five mortality rates declined from 95 deaths per 1,000 live births in the period 10-14 years prior to the survey to 58 per 1,000 in the period 0-4 years preceding the survey. The ratio of postneonatal to neonatal mortality decreased from 1.3 to 1.1 during the fifteen-year period before the survey, because of the more rapid decline in postneonatal deaths in the most recent five-year period.

Trends in mortality can also be studied using estimates based on the 1971, 1980, and 1990 population censuses; the 1987 NICPS, and the 1991, 1994, and 1997 IDHS. Infant mortality based on the census data is estimated indirectly using information on the number of children ever born and the number of children who died; estimates from the NICPS and IDHS are obtained from the birth history data. Figure 9.2 shows that in 27 years, the infant mortality rate has declined by 68 percent, from 142 deaths per 1,000 births in 1968 to 46 per 1,000 births in 1995.

Table 9.2 shows the trends in mortality by region based on the results of the 1987 NICPS, the 1991 IDHS, the 1994 IDHS, and the 1997 IDHS. Between 1991 and 1994, infant and child mortality declined in all three regions and regional variations narrowed; however, the 1997 IDHS results show that even though infant and child mortality have declined in all regions (except child mortality in DI Yogyakarta), the regional variations have become wider.

¹The projected infant mortality rate for 1993 was calculated based on the 1990 population census.

Note: Approximate calendar periods covered: 1987 NICPS (1977-1987), 1991 IDHS (1981-1991), 1994 IDHS (1984-1994) and 1997 IDHS (1987-1997).

Despite the fact that mortality rates in West Java have declined in recent years, this province continues to have the highest mortality in Java (see Table 9.2). At the same time, DI Yogyakarta generally has the lowest mortality in the Java-Bali region.

Children in Java-Bali have lower levels of infant and child mortality than children in Outer Java-Bali. This may be due to better health and medical facilities in the Java-Bali region than in the Outer Java-Bali regions.

9.4 Mortality Differentials

A number of socioeconomic, environmental, and biological factors influence infant and child mortality. Mosley and Chen's (1984) framework for the study of child mortality in developing countries outlines various proximate and socioeconomic determinants of infant mortality. In the following section, infant and child mortality differentials are discussed according to biodemographic and socioeconomic variables that were included in the 1997 IDHS. Several variables, namely age of the mother, parity, and birth interval, were used as the biodemographic determinants. The socioeconomic determinants, which operate through the biodemographic determinants to influence infant mortality, include place of residence and mother's educational attainment. Additionally, several variables related to health, such as the type of birth attendant and birth weight, as well as variation among provinces, are discussed.

Table 9.3 presents mortality rates by socioeconomic characteristics of the mother for the ten-year period preceding the survey, i.e., from 1987 to 1997. Children born to women living in urban areas have lower mortality rates than those born to women in rural areas. The same pattern was found in the 1987 NICPS, 1991 IDHS, and 1994 IDHS, for all ages at death and in all regions. The lower mortality rates in the urban areas may be related to the greater availability of health facilities.

Mother's level of education is closely associated with socioeconomic factors such as income, life style, health practices, nutrition, and housing and living conditions. Women who have limited education usually have low income and live in less sanitary housing conditions; thus, their children usually have a higher risk of morbidity and mortality. The 1997 IDHS data show that mother's educational attainment is inversely associated with childhood mortality levels; children of less-educated mothers generally have higher mortality than those born to better educated mothers.

Table 9.3 also shows the relationship of infant and child mortality to antenatal care and delivery assistance. Mortality among children whose mothers had neither antenatal care nor medical assistance at the time of delivery is noticeably highest, followed by that for children with either antenatal care or delivery assistance by a medical professional (except for neonatal mortality). As expected, childhood mortality is lowest for children of mothers who received antenatal care and were assisted by a medical professional at delivery. The same pattern was found in the 1991 IDHS and 1994 IDHS.

The relationship between infant and child mortality rates for the ten-year period prior to the survey (1987 to 1997) and various biodemographic variables can be observed in Table 9.4. These variables have been found to be associated with the level of infant and child deaths. Overall, except for childhood mortality, the rates for males are higher than those for females. For example, infant mortality rates for males are about 30 percent higher than those for females, while under-five mortality and neonatal mortality for males are about 20 percent higher than those for females. Sex differentials in childhood mortality were also observed since the 1987 NICPS.

Mother's age at birth can affect a child's chances of survival. The 1987 NICPS, 1991 IDHS, and 1994 IDHS results indicate that childhood mortality rates follow a U-shaped pattern according to mother's age. However, results of the 1997 IDHS show a different pattern. In general, rates are highest for children whose mothers are younger than 20 years at the time of delivery, and lowest among children whose mothers are 40-49 years. The rates of infant and child mortality to mothers age 30-39 years at the time of delivery are second highest.

Table 9.3 Infant and child mortality by background characteristics

Infant and child mortality rates for the ten-year period preceding the survey, by selected background characteristics, Indonesia 1997

Total	25.0	27.2	52.2	19.4	70.6

Note: The approximate calendar period covered is mid-1987 to mid-1997.

¹ Rates are for the five-year period preceding the survey.

Table 9.4 also shows that birth order affects a child's chances of survival. It is often hypothesized that first births and higher order births have higher mortality risks. However, the data indicate that mortality rates for first births are lower than those for second and third births. Except for neonatal mortality, the rates of mortality increase along with the increasing of the birth order; the higher the birth order, the higher the rates of mortality. For example, under-five mortality is 59 per 1,000 live births for first births; 66 and 76 per 1,000 live births for birth orders 2-3 and 4-6, respectively; and 124 per 1,000 live births for seventh and higher birth orders.

As expected, there is an inverse relationship between mortality rates and the interval since the previous birth; childhood mortality rates decline as the birth interval increases. The under-five mortality rates for children born less than two years after a previous birth are almost three times higher than those for children born after an interval of four or more years (135 compared with 48 deaths per 1,000 live births).

Table 9.4 Infant and child mortality by biodemographic characteristics

Infant and child mortality rates for the ten-year period preceding the survey, by selected biodemographic characteristics, Indonesia 1997

Biodemographic characteristic	Neonatal mortality (NN)	Postneonatal mortality (PNN)	Infant mortality ($_1q_0$)	Child mortality ($_4q_1$)	Under-five mortality ($_5q_0$)

2-3 yrs	22.4	29.4	51.8	21.3	72.0
4 yrs +	15.2	16.6	31.8	16.7	48.0
Size at birth¹					
Very small	193.8	55.9	249.7	9.2	256.6
Small	39.8	30.6	70.4	13.8	83.2
Average or larger	15.9	22.5	38.4	11.2	49.2

Note: The approximate calendar period covered is mid-1987 to mid-1997. Figures in parentheses are based on 250-499 births.

¹ Rates are for the five-year period preceding the survey.

Except for childhood mortality, the probability of dying for infants who were considered to be *very small* at birth by their mothers is much higher than that for infants described as *small* or *average or larger* at birth (see Table 9.4). The period immediately after birth is critical, especially for babies reported to be very small. However, it should be noted that the information on infant size at birth presented here is subjective (because it is based on the judgment of mothers) and is not comparable with actual birth weight. The neonatal mortality rates for infants who were judged to be *very small* at birth by their mothers are twelve times higher than those for infants who were reported to be in *average or larger* at birth (194 compared with 16 deaths per 1,000 live births). This ratio for infant mortality and under-five mortality is only seven and five times, respectively.

In a country as large and geographically dispersed as Indonesia, considerable variation in mortality among regions and provinces is not surprising. Table 9.5 shows patterns of provincial mortality in the 1997 IDHS. The lowest infant mortality rates in the country are found in DI Yogyakarta, DKI Jakarta, and Maluku (under 30 deaths per 1,000 live births), and the highest are in West Nusa Tenggara (111 per 1,000). West Kalimantan, South Kalimantan, Bengkulu, Central Sulawesi, and Southeast Sulawesi have relatively high levels of infant mortality—70 deaths or more per 1,000 live births.

Central Kalimantan	(29.4)	25.9	55.3	14.4	68.9
East Kalimantan	(29.3)	21.4	50.7	16.4	66.2
Central Sulawesi	(43.7)	50.8	94.5	29.7	121.4
Southeast Sulawesi	*	51.8	78.1	17.4	94.2
Maluku	(11.1)	18.4	29.5	19.5	48.4
Irian Jaya	(32.2)	32.5	64.7	29.5	92.3
Total	25.0	27.2	52.2	19.4	70.6

Note: The approximate calendar period covered is mid-1987 to mid-1997. Figures in parentheses are based on 250-499 births. An asterisk indicates that a figure is based on fewer than 250 births and has been suppressed.

In Java-Bali, West Java is the only province that has infant and child mortality rates higher than those for Indonesia as a whole. The variation in infant and child mortality among the provinces in the Outer Java-Bali regions is greater than among the provinces in Java-Bali.

9.5 High-Risk Fertility Behavior

Table 9.6 presents the distribution of women and children according to fertility behavior characteristics that place children at an elevated risk of dying. Children at elevated risk include those whose mothers are too young or too old when they give birth, those of high birth order, and those born after short birth intervals. Assumptions about these risks are that the physiological condition of young women (18 years or younger) is not sufficiently mature for healthy reproduction, which leads to greater risk of neonatal death. On the other hand, women age 35 years or older may be physically debilitated as a result of having many children, which may adversely affect the baby's health. Short birth intervals can affect the health of both

children, which may adversely affect the baby's health. Short birth intervals can affect the health of both mother and child and reduce the baby's chances of survival. Table 9.6 also shows the relative risk of dying for children born in the five years preceding the survey by comparing the proportion dead in each high-risk category to the proportion dead among children who are not in any high-risk category.

Table 9.6 High-risk fertility behavior

Percent distribution of children born in the five years preceding the survey by category of elevated risk of mortality, and the percent distribution of currently married women at risk of conceiving a child with an elevated risk of mortality, by category of increased risk, Indonesia 1997

Risk category	Births in 5 years preceding the survey		Percentage of currently married women ^a
	Percentage of births	Risk ratio	
Not in any high-risk category	59.9	1.00	35.2 ^b
Single high-risk category			
Mother's age < 18	4.8	2.20	0.7
Mother's age > 34	2.4	1.32	10.9
Birth interval < 24 months	6.0	1.94	8.5
Birth order > 3	13.8	1.29	9.2
Subtotal	27.1	1.60	29.3
Multiple high-risk category			
Age < 18 & birth interval < 24 months ^c	0.2	9.09	0.2
Age > 34 & birth interval < 24 months	0.1	0.60	0.2
Age > 34 & birth order > 3	8.7	1.32	29.0
Age > 34 & birth interval < 24 & birth order > 3	1.2	4.06	2.4
Birth interval < 24 & birth order > 3	2.8	2.84	3.7
Subtotal	13.0	2.03	35.5
In any high-risk category	40.1	1.74	64.8
Total	100.0	-	100.0
Number of births	16,080	-	26,886

Note: Risk ratio is the ratio of the proportion dead of births in a specific high-risk category to the proportion dead of births *not in any high-risk category*.

^a Women were assigned to risk categories according to the status they would have at the birth of a child, if the child were conceived at the time of the survey: age less than 17 years and 3 months, age older than 34 years and 2 months, latest birth less than 15 months ago, and latest birth of order 4 or higher.

^b Includes sterilized women

^c Includes the combined categories Age < 18 and birth order > 3.

Table 9.6 shows that 40 percent of children born in the five years preceding the survey have an elevated risk of dying; 27 percent are in a single high-risk category, while 13 percent are in a multiple high-risk category. Among children in single high-risk categories, 14 percent are fourth births or higher, 6 percent are children born less than two years after a prior birth, and 5 percent are children born to mothers younger than 18 years. Among children in multiple high-risk categories, 9 percent were born to mothers 35 or older and were birth order 4 or higher.

The second column in Table 9.6 presents risk ratios for children in various risk categories. Children in the single high-risk categories have a 1.6 greater risk of dying prematurely than children who are not in

any high-risk category, and children in multiple high-risk categories have twice the risk of dying as those who are not in any high-risk category. The highest mortality risks are found in the combination of early childbearing and short birth interval (9.0), while the lowest mortality risk is found among births with short birth interval and late childbearing (0.6).

The last column of Table 9.6 presents the distribution of currently married women according to category of increased risk if they were to conceive at the time of the survey. The table indicates that about two in three currently married women are at risk of conceiving a child with an elevated risk of dying; 29 percent of women are at risk because of a single factor, while 36 percent of women have multiple risk factors. The most likely risks are high birth order combined with late childbearing (29 percent of currently married women), giving birth at age 35 years or older (11 percent), high birth order (9 percent), and short birth intervals (9 percent).

CHAPTER 10

MATERNAL HEALTH

This chapter presents findings on maternal health--antenatal care and delivery assistance. In line with the program to improve maternal health and to make maternal health care services more accessible, besides health centers in every subdistrict, ambulatory health services, auxiliary health centers (*puskesmas pembantu*), health posts (*posyandu*), and village delivery posts (*polindes*) have been established. In village delivery posts, antenatal care and delivery assistance are provided by trained traditional birth attendants under the supervision of a midwife.

10.1 Antenatal Care

Table 10.1.1 shows the percent distribution of live births in the five-year period prior to the survey by type of antenatal care received during pregnancy according to selected background characteristics. In Indonesia, antenatal care is defined as pregnancy-related health care provided by medical professionals (doctor, nurse, or midwife), excluding traditional birth attendants and friends. Although each live birth may have received antenatal care from multiple types of providers, in this report the evaluation of maternal health care for early detection of high-risk pregnancies is based on the most qualified provider. The place of antenatal care service, recorded in the survey, is the most frequently visited service.

Among 28,810 ever-married women age 15-49 interviewed in the survey, 13,170 were mothers who had a total of 16,217 live births in the five years preceding the survey. Eighty-nine percent of these births were to mothers who received antenatal care from a medical professional—79 percent were cared for by a nurse/midwife or an auxiliary nurse/midwife.

Antenatal coverage is slightly lower among births to mothers age 35 and older. Third or lower order births are more likely to receive antenatal care from medical professionals than higher order births. Births to mothers living in urban areas or in Java-Bali are more likely to receive antenatal care from medical professionals than other births. Ninety-two percent of live births in Java-Bali had antenatal care from medical professionals, compared with 88 percent in Outer Java-Bali I and 83 percent in Outer Java-Bali II.

There is a strong relationship between mother's education and antenatal care. Seventy-one percent of births to mothers with no education received antenatal care from medical professionals, compared with only 97 percent of children whose mothers had some secondary education. The corresponding proportions for children whose mothers had some primary education and who have completed primary school are 83 percent and 91 percent, respectively.

Mothers living in the urban areas and those having some secondary education are more likely to receive antenatal care from a doctor than other mothers. Although there is little variation in antenatal care coverage by medical professionals between regions, there are sharp differentials between urban and rural areas within regions.

Table 10.1.2 shows the provincial differentials in antenatal care coverage. Virtually all women in DKI Jakarta and DI Yogyakarta had antenatal care during pregnancy. Antenatal care coverage was 90 percent or higher in East Java, Bali, West Sumatra, South Sumatra, Lampung, West Nusa Tenggara, North Sulawesi, and East Kalimantan. On the other hand, antenatal coverage was less than 70 percent in Jambi and Maluku, where a large proportion of women received antenatal care from traditional birth attendants. It is interesting to note, however, that 28 percent of births in the five years preceding the survey in East Timor did not receive any antenatal care.

Table 10.1.1 Antenatal care: background characteristics

Percent distribution of live births in the five years preceding the survey by source of antenatal care during pregnancy, according to selected background characteristics, Indonesia 1997

10.2 Place of Antenatal Care, Number of Antenatal Care Visits, and Stage of Pregnancy

Table 10.2.1 indicates that 52 percent of children were born to mothers who received antenatal care from government health services, of which health centers are the most often visited (39 percent).

Rural women are more likely to visit a public health facility for antenatal care, while urban women go to a private facility. The facility most often used by rural women is the health center, while urban women

use the services of a private midwife. Private services are more frequently utilized by better educated women than those with less education; the comparison is 54 percent for women with secondary or higher education and 19 percent for women with no education. Since village delivery posts (polindes) are available only in limited areas, they have limited utilization (2 percent)—less than 1 percent in the urban areas and 3 percent in the rural areas.

TBA = Traditional birth attendant

Table 10.2.2 shows provincial variations in the utilization of health services for antenatal care. In DKI Jakarta, Bali, North Sumatra, West Sumatra, and Lampung, more than 50 percent of children were born to mothers who had antenatal care from private health facilities, among which private midwife's clinics were the most frequently visited.

The Indonesian maternal health program recommends that pregnant women have at least four antenatal care visits during pregnancy, according to the following schedule: one visit in the first trimester, one visit in the second trimester, and two visits in the third trimester. Table 10.3 shows that the median number of antenatal visits was 6.6, well above the recommended number. Sixty-nine percent of births were to mothers who had four or more antenatal care visits from a medical professional (Figure 10.1).

TBA = Traditional birth attendant

TBA = Traditional birth attendant

Table 10.3 also shows that four in ten pregnant women started having an antenatal check, as recommended, in the first trimester, while more than half (52 percent) had their first antenatal care visit in the second and third trimester. Eleven percent of births were to mothers who had no professional antenatal care. The median number of months at the first antenatal care visit was 3.3 months, which means that half of the pregnant women had their first antenatal care earlier than 3.3 months of pregnancy.

Table 10.3 Number of antenatal care visits and stage of pregnancy

Percent distribution of live births in the five years preceding the survey by number of antenatal care (ANC) visits, and by the stage of pregnancy at the time of the first visit, according to type of antenatal care, Indonesia 1997

10.3 Tetanus Toxoid Vaccination

Immunization of pregnant women is a coordinated activity of the Expanded Program on Immunization (EPI) and the maternal and child health care (MCH) units in the Ministry of Health, which recommends that women receive two tetanus toxoid injections during the first pregnancy. Booster injections are given once during each subsequent pregnancy to maintain full protection. In recent years, tetanus toxoid immunization was also given to women before marriage, so that any pregnancy occurring within 3 years of their marriage would be protected against tetanus. Antenatal cards, on which tetanus toxoid immunizations are recorded, are distributed to every pregnant woman as a lifetime pregnancy and delivery history record keeper.

Among 16,217 live births in the five years preceding the survey, 53 percent were to mothers who received antenatal cards. Antenatal card coverage is higher in urban areas than in rural areas (62 percent compared with 50 percent). Women in Java-Bali are more likely to have an antenatal card than women in the Outer Islands of Java-Bali (58 percent compared with 45 and 53 percent). The percentage of mothers with antenatal cards is higher among those with higher education (Table 10.4.1).

Since the findings above show that antenatal cards were not widely distributed, tetanus toxoid immunization coverage cannot be estimated from vaccination cards alone. Respondents' recall

is used to supplement information on immunization status. As a result, the proportion of births that are fully protected against tetanus may be underestimated. In addition, some women may have received tetanus toxoid immunization before marriage or during a previous pregnancy, so they might not need another injection or a booster immunization. On the other hand, women may incorrectly report other types of injections as tetanus immunization, which will overestimate the level of immunization coverage. It is difficult to evaluate the extent to which each of these biases exist in the DHS data. Therefore, the information on tetanus immunization should be regarded as an approximate indicator of the level of coverage.

Overall, of births in the five years before the survey, 53 percent were to mothers who received two or more tetanus toxoid injections during pregnancy, 18 percent received one injection, and 26 percent received no injection. The coverage of tetanus toxoid injection tends to decrease as the mother's age and the birth order increase (Table 10.4.1). The percentage of births unprotected against tetanus neonatorum is substantially higher in rural areas (29 percent) than in urban areas (18 percent) and is higher in the Outer Java-Bali regions (32 and 28 percent) than in Java-Bali (23 percent). Tetanus toxoid injection coverage increases with mother's education. While 45 percent of births to mothers with no education and 37 percent of births to mothers with some primary education never receive any tetanus toxoid injection, the corresponding proportion for births to mothers with some secondary education is only 16 percent.

Figure 10.1
Number of Antenatal Care Visits and Gestation
Period at First Visit for Births in the
Five Years Preceding the Survey

IDHS97

In the five years preceding the survey, the proportion of births for which an antenatal card was presented varied significantly by province, from 21 percent in North Sumatra to 75 percent or more in DI Yogyakarta and Bali. Tetanus immunization coverage also varies among provinces. While less than 10 percent of births in Bali and North Sulawesi were to mothers who did not receive a tetanus toxoid injection during pregnancy, more than 50 percent of births in North Sumatra were to unimmunized mothers (Table 10.4.2).

10.4 Iron Pills

Anemia during pregnancy is still prevalent in Indonesia. Iron pills are distributed to women during their antenatal care visits to health care services. The maternal health program of the Indonesian Ministry of Health recommends that pregnant women take at least 90 iron pills during their pregnancy. In order to evaluate this program, in the 1997 IDHS, all women who gave birth during the five years before the survey were asked whether they had received iron pills during their last pregnancy and, if so, how many they had taken.

Of the 13,170 births in the five years preceding the survey, 24 percent of the mothers took 90 or more iron pills during pregnancy, while 17 percent took none (Table 10.5). Older mothers, mothers of higher order births, and less educated mothers are less likely to take iron pills during their pregnancy.

Iron pills are better distributed in urban areas and in Java-Bali, than in other areas. For 20 percent or more of recent births in rural areas and in Outer Java-Bali, women did not take any iron pills during their pregnancy, while mothers in urban areas and in Java-Bali region took at least 90 iron pills during pregnancy for more than 30 percent of births.

Table 10.4.1 Tetanus toxoid vaccinations: background characteristics

All births	26.2	18.4	53.4	2.0	100.0	16,217	53.3

While nine in ten mothers with no antenatal care and nine in ten mothers who receive antenatal care from a traditional birth attendant never get any iron pills during their pregnancy, only 8-11 percent of mothers who go to a government or a private health service facility for antenatal care get no iron pills during their pregnancy. Mothers who have their first antenatal visit in the first trimester are more likely to have taken 90 or more iron pills during their pregnancy than those who start antenatal care later.

10.5 Place of Delivery

Despite the growing availability of village delivery posts (*polindes*), four in five births in Indonesia are still delivered at home, including 7 percent delivered in a midwife's home (an increase of 2 percentage points since 1994). Only 9 percent of births in the five years preceding the survey were delivered in a government health service facility (government hospitals, village delivery posts, and health centers) and 19 percent were delivered in private hospitals or clinics (including the 7 percent delivered in a midwife's home) (Figure 10.2).

Table 10.5 Iron tablets taken during pregnancy

Figure 10.2
Delivery Characteristics of Births in
the Five Years Preceding the Survey

IDHS97

Births to women in high-risk age groups—under 20 years or 35 years and over—are more likely to be delivered at a private home than births to women age 20-34. For women under age 20 the proportion is 83 percent, for those age 35 and over it is 78 percent, and for women age 20 to 34 it ranges from 67 to 72 percent. Higher order births are more frequently delivered at home—89 percent among seventh and higher order births compared with 65 percent among first order birth. This implies that a relatively large proportion of high-risk births are delivered at home (Table 10.6.1).

Births in rural areas are twice as likely to be delivered at home as those in urban areas (84 percent compared with 41 percent). Fifteen percent of births in urban areas are delivered in a midwife's home. The percentage of home deliveries in the Outer Java-Bali regions (76 and 82 percent) is higher than that in Java-Bali (69 percent). Deliveries in a midwife's home are very popular in urban Java-Bali (20 percent). Births to mothers who have no education are twice as likely to be delivered at home as births to mothers who have some secondary education (92 percent and 48 percent, respectively). The utilization of private hospitals or clinics for delivery is considerably higher in urban than in rural areas. It is also higher for first through third deliveries, and among births to mothers with some secondary education.

Significant variations are found in the place of delivery by province (Table 10.6.2). A majority of births (more than 60 percent) are delivered at home in all provinces except in DKI Jakarta (20 percent), DI Yogyakarta (43 percent), Bali (28 percent), and West Sumatra (51 percent). In DKI Jakarta, 80 percent of births occur in health facilities, among which 56 percent are delivered in private hospitals, clinics, or midwife's homes and 23 percent in government hospitals or health centers. Similarly, in DI Yogyakarta, Bali, and West Sumatra, more births are delivered in private facilities than in government facilities.

10.6 Assistance during Delivery

In the survey, respondents were asked about all types of assistance attending the delivery. If more than one type of delivery attendant was recorded, only the least qualified delivery attendant was considered for tabulation, since they are usually the first choice to assist during delivery. Only complicated cases are referred to the more qualified attendant.

Forty-three percent of births in the five years before the survey were assisted by a doctor or a nurse/midwife, and 57 percent of births were assisted by non-medical staff—54 percent by a traditional birth attendant and 3 percent by a relative (Table 10.7.1 and Figure 10.2). Births to young mothers, high birth orders, those in rural areas, those to mothers with no education, and to mothers who receive no antenatal care are more likely to be assisted by non-medical staff than other births.

¹ If the respondent mentioned more than one attendant, only the *least* qualified attendant was considered (see text for explanation).

Traditional birth attendants still have a very important role in delivery assistance, especially in the rural areas (65 percent), in the Java-Bali region (57 percent), to mothers with no education or some primary education (74 percent), as well as to mothers with no antenatal care (83 percent).

The coverage of deliveries assisted by traditional birth attendants varies among provinces, from 9 percent in DKI Jakarta to 78 percent in West Nusa Tenggara (Table 10.7.2). Overall, 3 percent of births were assisted by relatives, which may have greater risk for the mother and baby, than those assisted by traditional birth attendants, because relatives generally have no training and are less experienced in assisting delivery than traditional birth attendants. Some provinces have a high prevalence of relative-assisted deliveries, e.g., East Nusa Tenggara (11 percent), Irian Jaya (26 percent), and East Timor (57 percent). The high prevalence of deliveries assisted by relatives in Irian Jaya and East Timor was also noted in past IDHS.

¹ If the respondent mentioned more than one attendant, only the *least* qualified attendant was considered (see text for explanation).

10.7 Delivery Characteristics

In Indonesia, caesarean sections generally are performed under certain medical indications and to terminate complicated deliveries. In this survey, only 4 percent of births were delivered by a caesarean section (Table 10.8.1). The percentage of caesarean section is higher among older women, lower birth orders, and mothers with some secondary education. In urban areas, 6 percent of births were delivered by a caesarean section, compared to 4 percent in rural areas. Deliveries in Java-Bali are more likely to be by a caesarean section than in Outer Java-Bali regions (5 percent compared with only 3 percent).

Table 10.8.1 Delivery characteristics: background characteristics

Among births in the five years preceding the survey, the percentage of deliveries by caesarean section, the percentage of premature births, and the percent distribution by birth weight and by the mother's estimate of baby's size at birth, according to background characteristics, Indonesia 1997

According to respondents' reports, about 3 percent of births were delivered prematurely. This figure is relatively low in comparison to the actual percentage of low birth weight deliveries (8 percent) and the percentage of newborns reported as small by their mothers (14 percent).

Since most deliveries are attended by traditional birth attendants at home, birth weights were not reported for 38 percent of births in the 1997 IDHS. This proportion is five times higher in rural than in urban areas (48 percent and 10 percent, respectively). Among babies who were weighed at birth, 8 percent were under 2.5 kilograms (i.e., low birth weight). The prevalence of low birth weight is higher among children born to mothers less than 20 years than among those born to older mothers (12 percent compared with 8 percent or less). The prevalence of low birth weight fluctuates with birth order. It is high (10 percent) among first-born children, declines to 6 percent among second and third children, and increases again to 8 percent among fourth and higher order births.

The prevalence of low birth weight declines as mother's educational level increases; 11-12 percent among children born to mothers with no education or some primary education, compared with 8 percent or less among children born to mothers with complete primary or higher education.

There is a slight difference in the prevalence of births with low birth weight by area of residence—8 percent in rural areas and 7 percent in urban areas. In the Outer Java-Bali II region, 9 percent of births weighed less than 2.5 kilograms, compared with 8 percent in Java-Bali and 7 percent in Outer Java-Bali I region.

Survey respondents were asked their perception of the size of their newborns. Approximately 14 percent of births were perceived by their mothers as being either *very small* or *smaller than average*. Younger mothers and those with less education are more likely to report that their newborn is *smaller than average* (Table 10.8.1).

The prevalence of low birth weight ranges between 10 and 16 percent in 6 provinces, namely West Java, West Kalimantan, South Sulawesi, East Nusa Tenggara, Central Kalimantan, and Central Sulawesi (Table 10.8.2).

10.8 Complications of Delivery

To identify complications associated with delivery, respondents were asked about certain signs and symptoms that they had experienced to all live births during the five years prior to the survey. Table 10.9 shows that 26 percent of births were accompanied by complications at delivery. Prolonged labor was reported for 22 percent of births, excessive bleeding for 7 percent and, vaginal infection for 4 percent. Two percent of births were accompanied with maternal convulsions.

In general, delivery by a medical professional is more likely to be reported involving complications, in particular prolonged labor and excessive bleeding (Table 10.9 bottom panel). As expected, the prevalence of delivery complications is higher (35 percent) among deliveries with caesarian section, mostly due to prolonged labor (25 percent) and excessive bleeding (14 percent). Among deliveries resulting in neonatal deaths, 38 percent were accompanied with complications including prolonged labor (32 percent), excessive bleeding (13 percent), vaginal infection (13 percent), and maternal convulsions (4 percent).

There are negligible differences in the prevalence of delivery complications by respondents' type of residence.

CHAPTER 11

IMMUNIZATION OF CHILDREN

The Expanded Program of Immunization, launched by the Indonesian Ministry of Health in 1977, recommended that all children receive immunization against six diseases: tuberculosis (BCG), diphtheria, pertussis, tetanus (DPT), polio, and measles. In the sixth Five-Year Development Plan (1993-94 to 1997-98), efforts to reduce childhood morbidity and mortality by improving the immunization coverage among children have been continued, in particular with the National Mass Immunization Campaigns in 1996 and 1997.

Infants brought to health centers or to health posts for postnatal care are provided with a health card on which feeding, growth, and immunization information can be recorded. The type and date of vaccinations are also recorded in a registration book maintained by the field vaccinators. It is important that cards be kept by the mothers, to enable them to monitor their children's growth and to keep a record of immunization schedules. However, not all mothers have kept the cards. Furthermore, not all infants receive postnatal care and, therefore, have never received a health card.

In this survey, immunization information was collected for children born in the five years before the survey. For children with a health card, the interviewer asked to see the card, then copied the vaccination dates onto the questionnaire. If the child had never received a health card or if the mother was unable to show the card to the interviewer, the mother was asked questions about the types of immunizations her children received—i.e., BCG, DPT, polio, and measles vaccines—and the number of doses of DPT and polio vaccines received.

11.1 Health Cards

Table 11.1.1 shows the percentage of children for whom mothers reported they had a health card and whether or not it was seen by the interviewer. Overall, among children age 12-59 months, 84 percent had been given a health card, but only 19 percent had health cards that were actually seen by the interviewer. Sixty-one percent were reported by their mothers to have cards, but these were not seen by the interviewer. The large proportion of children reported to have cards but for whom the mother could not show the card to the interviewer reflects the fact that many cards are kept at the health centers or kept by health cadres or are discarded or lost in the respondent's house.

The percentage of children whose mothers could show their health cards declines with increasing age of the children. The decline with age may reflect either an increase in the use of health cards over time or the fact that the health cards of older children are more likely to have been lost or discarded. There is no difference in health card coverage by the sex of the child; however, the percentage seen by the interviewer is higher for children of low birth order, urban children, and children of educated women. Only 12 percent of children born to mothers with no education were able to show a health card to the survey interviewer, compared with 24 percent of women with some secondary education (Figure 11.1).

Children in Outer Java-Bali I are less likely to have ever had a health card than children in Java-Bali region (Table 11.1.2). The percentage of children who have a health card varies by province, ranging from a low of 69 percent in North Sumatra to close to 100 percent in DI Yogyakarta, while the percentage with cards seen by the IDHS interviewers ranges from 5 percent in Dista Aceh to 39 percent in DI Yogyakarta. Provinces in which health card coverage is relatively high (95 percent or higher) are North Sulawesi, East Nusa Tenggara, and East Kalimantan. However, the percentage of children for whom a health card was issued but was no longer available in the respondent's house is particularly high in DKI Jakarta (9 percent).

Table 11.1.1 Health cards: background characteristics

Percent distribution of children age 1-4 years by presence of a health card, according to background characteristics, Indonesia 1997

Total	19.3	60.8	3.7	16.3	100.0	12,220

11.2 Immunization Coverage

Table 11.2 presents vaccination coverage rates according to information recorded on health cards (top panel), information from mothers (middle panel), and both sources (bottom panel). The table shows that among children age 12-23 months whose health cards were seen, the percentage fully immunized was 69 percent (see top panel). The highest coverage rates (85 percent or higher) are for BCG, DPT1 and polio1 (Figure 11.2). Comparison with the levels reported in 1994 IDHS indicates that immunization coverage as recorded on health cards does not show any significant difference.

Immunization coverage rates based on mothers' reports are considerably lower than those based on health cards (Table 11.2 middle panel). For example, the percentage completely immunized is 53 percent, 20 percent lower than that recorded on the health card. For children age 12-23 months, the highest coverage

rate of individual vaccines is for polio1 (91 percent), BCG (80 percent), and DPT1 (76 percent). In general, immunization coverage rates based on mothers' reports are higher than those recorded in the 1994 IDHS.

Table 11.1.2 Health cards: region and province

Percent distribution of children age 1-4 years by presence of a health card, according to region and province, Indonesia 1997

11.3 Immunization by Background Characteristics

Table 11.3.1 shows vaccination coverage by background characteristics among children age 12-23 months at the time of the survey. The figures in this table are based both on health cards and mothers' reports. The table also shows health card coverage.

Since girls are slightly more likely than boys to get to the third doses of DPT and polio, as well as measles vaccines, female children are more likely to have received full immunization than male children (56 percent compared with 53 percent).

Figure 11.1
Health Card Coverage by Child's Age, Region
and Mother's Education

IDHS97

Except for first births, the percentage of children receiving each vaccine decreases with increasing birth orders and increases with increasing level of mother's education. Thirty-nine percent of children whose mothers have no education have been fully immunized, compared with 69 percent of children whose mothers have some secondary education. Urban children are more likely to be fully vaccinated than rural children (66 percent vs. 50 percent). Despite the relatively high immunization coverage among children in the urban areas, only 37 percent of mothers were able to show the health card.

In 1997, children in Outer Java-Bali II were more likely to be fully immunized than children in other regions (see Table 11.3.2). This pattern is similar to that recorded in the 1994 IDHS but different from the results of the 1991 IDHS, when immunization coverage in Java-Bali was the highest in the country. Within Java-Bali, DI Yogyakarta shows the highest levels of full immunization coverage (87 percent), while West Java has the lowest full immunization coverage (42 percent) in the region. North Sumatra has the lowest coverage of all the provinces (36 percent fully immunized).

The types of immunization received also vary by province. However, for BCG and DPT1 vaccination, Jambi consistently shows the lowest level of immunization coverage, while for polio3 vaccination, eight provinces (West Java, Central Java, Dista Aceh, North Sumatra, South Sulawesi, East Timor, Maluku, and Central Kalimantan) show immunization coverage of less than 70 percent. Fifteen percent or more of children 12-23 months have never been immunized in South Sulawesi, East Timor, and Maluku.

Health card coverage also varies widely by province, ranging from 9 percent in East Timor to 58 percent in DI Yogyakarta.

Table 11.2 Vaccinations by source of information

Among children one to four years of age, the percentage who had received specific vaccines at any time before the survey, by source of information (health cards, mothers' reports, or both) and current age of child, Indonesia 1997

Figure 11.2
Immunization Coverage Among Children Age 12-23 Months

Note: Full immunization refers to children who have received BCG, measles, and three doses each of DPT and polio vaccines.

IDHS97

11.4 Immunizations by First Year of Life

The immunization series should be completed by the end of the first year of life. Therefore, immunization coverage for the first 12 months is evaluated in Table 11.4. The top panel presents immunization coverage based on information recorded on children's health cards, while the bottom panel combines, health card information and mothers' reports. Information from health cards and mothers' reports shows that 46 percent of children age 1 to 4 years have been fully immunized by age one. This rate is slightly higher than the 42 percent reported in 1994.

The patterns of immunization coverage by current age of the child may be interpreted as reflecting time trends in immunization program activities. Based on information from health cards and mothers' reports, the data show increasing coverage among younger children for all types of immunization except measles, which has declined slightly. With reference to children age 12-23 months (born in the period 1996-1997), the percentage fully immunized in the first year of life is 47 percent, compared with 46 percent among children age 48-59 months (born in the period 1989-1990). The proportion of children who have received no vaccinations in the first year of life has been decreasing over time, from 10 percent to 7 percent.

11.5 Distribution of Vitamin A for Children

It is recommended that all children under five years take high-dose vitamin A supplements to prevent vitamin deficiency that may cause xerophthalmia. Vitamin A tablets are distributed at 6-month intervals to children age 12-59 months. The distribution of vitamin A is recorded on the child's health card.

The top panel in Table 11.5 shows the coverage of vitamin A as recorded on health cards by the children's age. Overall, 46 percent of children age 12-59 months for whom a health card was seen have never received high-dose vitamin A. Younger children are less likely to have received vitamin A than older

children. While 56 percent of children 12-23 months have never received vitamin A, the corresponding percentage for children 48-59 months is 30 percent. As vitamin A is recommended to be distributed every 6 months, all children 12-23 months should have received at least one dose of vitamin A. However, more than half of these children have never received any vitamin A. Among children 24-35 months, 44 percent never received the vitamin, and only 15 percent received three or more doses of vitamin A. These figures show that for the majority of children under age five, the distribution of vitamin A has not followed the recommended schedule.

Table 11.3.1 Vaccinations: background characteristics

Note: The DPT coverage rate for children without a written record is assumed to be the same as that for polio vaccine since mothers were specifically asked whether the child had received polio vaccine.

¹ Polio 0 is given at birth.

² Children who are fully vaccinated (i.e., have received BCG, measles, and three doses each of DPT and polio vaccines).

First-order children and seventh- or higher order children are more likely to have received high-dose vitamin A (59 and 60 percent, respectively) compared with other children (Table 11.5). There is no difference in the distribution of high-dose vitamin A by type of residence; however, the coverage was higher in the Outer Java-Bali regions (62 percent or higher) than in Java-Bali (49 percent).

Children of better educated women are more likely to have received high-dose vitamin A than children of women with less education. The type of assistance during delivery makes little difference in a child's chance of receiving high-dose vitamin A.

Table 11.4 Vaccinations in first year of life

CHAPTER 12

CHILDHOOD DISEASES

12.1 Acute Respiratory Infection

Acute lower respiratory tract infection, primarily pneumonia, is a common cause of morbidity and death among children under five years of age. Pneumonia is characterized by cough with difficult or rapid breathing and chest in-drawing. Severe pneumonia needs hospitalization; otherwise, ambulatory treatment with antibiotics is recommended. Early diagnosis and treatment with antibiotics can prevent a large proportion of deaths caused by acute lower respiratory infection. It should be noted that in this survey identification of acute respiratory infection is based on the respondent's perceptions of the respiratory symptoms suffered by the child.

Prevalence and Incidence¹ of Acute Respiratory Infection (ARI)

Data from the 1997 IDHS indicate that the prevalence of a cough in the two weeks preceding the survey among children under five is 27 percent, and the incidence is 24 percent. The prevalence of a cough with rapid breathing in the two weeks prior to the survey is 9 percent, and the incidence is 8 percent (Table 12.1.1).

While higher rates of prevalence and incidence are observed among children age 6 to 23 months, little variation is found by other characteristics. Higher order children (seventh or higher) are less likely than low-order children to have a cough. Children born to mothers with no education have slightly lower prevalence and incidence rates of cough than children of mothers who have attended school. While urban children in all regions are more likely than rural children to have a cough, there is little variation in the prevalence of cough with rapid breathing (see Figure 2.1). The prevalence and incidence of cough show negligible differences by region.

Table 12.1.2 shows the prevalence and incidence of cough by province. Nine out of 27 provinces—West Sumatra, South Sumatra, West Nusa Tenggara, North Sulawesi, Riau, Bengkulu, East Nusa Tenggara, Central Kalimantan, and Irian Jaya—have a high prevalence of both cough (30 percent and over) and cough with rapid breathing (10 percent and over). Three provinces, DKI Jakarta, East Java, and East Kalimantan have high prevalence of cough (30 percent and over), and relatively low prevalence of cough with rapid breathing (less than 10 percent). Bali, Dista Aceh, North Sumatra, Jambi, and Central Sulawesi have high prevalence of cough with rapid breathing (10 percent and over), and relatively low prevalence and incidence of cough (less than 30 percent). In general, high prevalence of cough is accompanied by a high incidence.

Treatment of Acute Respiratory Infection

Table 12.2.1 shows that seven in ten children with cough and rapid breathing in the two weeks preceding the survey were taken to a health facility or provider, such as hospital, health center, health post (*posyandu*), private clinic, doctor, nurse, or midwife. Twenty-two percent of children received self-treatment (medicine from a pharmacy or drug store), and 8 percent received no treatment. A small percentage of ill children (1 percent) were taken to a traditional healer.

¹Prevalence refers to the percentage of children having ARI in the two weeks preceding the survey; incidence refers to the percentage of children who became sick with ARI in the two weeks preceding the survey.

Table 12.1.1 Prevalence and incidence of acute respiratory infection: background characteristics

Among all children under five years of age, the prevalence of cough and cough accompanied by rapid breathing, and the incidence of cough and of cough accompanied by rapid breathing, according to background characteristics, Indonesia 1997

Among infants under 6 months of age with cough and rapid breathing, 63 percent were taken to a health facility, one in five received no treatment, and 2 percent were taken to a traditional healer. There is little variation in the treatment of cough with rapid breathing, according to the sex or birth order of the child.

Urban children are more likely than rural children to be taken to a health facility when they have a cough with rapid breathing. Children of better educated mothers tend to be taken to a health facility for treatment of cough more often than children of mothers with less education, and the former are also less likely to be self-treated.

Children in the Outer Java-Bali I region who have cough with rapid breathing are more likely to be taken to a health facility than children in the Java-Bali and Outer Java-Bali II regions (72 percent, compared with 67 percent and 68 percent). Nineteen percent or more of children with cough and rapid breathing received no treatment in three provinces, South Sulawesi, Bengkulu, and Southeast Sulawesi (Table 12.2.2). Thirty percent or more of children with cough and rapid breathing received self-treatment in West Java, Lampung, South Kalimantan, and Central Sulawesi.

Figure 12.1
Prevalence of Cough and Rapid Breathing

12.2 Prevalence and Treatment of Fever

Information about the presence of fever in children under five years was recorded in the survey, although the causes of fever were not specified. Various infectious diseases are accompanied by fever. In Indonesia, the most common diseases with fever are malaria, respiratory and intestinal infections, measles, and typhoid.

Table 12.3.1 shows that the overall prevalence of fever (including children who also had cough, rapid breathing, or diarrhea) is 26 percent, and the prevalence of fever only is 6 percent. The prevalence of any fever is highest among infants age 6-11 months (39 percent), while that of fever only is 10 percent. There are negligible differences in the prevalence of any fever by sex of child, birth order, residence, and mother's education.

Since fever may accompany cough and diarrhea, the treatment of any fever may overlap with the treatment of cough and diarrhea. Therefore, in the analysis, treatment of fever refers to children with fever only, without cough or diarrhea.

Fifty-eight percent of children with fever only were taken to a health facility for treatment, 24 percent received self-treatment, and 15 percent received no treatment (Figure 12.2). Infants under 6 months of age with fever are less likely to be treated than older children—38 percent were not treated, compared with 11-16 percent among older children.

Table 12.1.2 Prevalence and incidence of acute respiratory infection: region and province

Among children under five years of age, the prevalence of cough and cough accompanied by rapid breathing, and the incidence of cough and cough accompanied by rapid breathing, according to region and province, Indonesia 1997

Region and province	Prevalence		Incidence		Number of children
	Cough	Cough and rapid breathing	Cough	Cough and rapid breathing

East Kalimantan	31.2	6.3	24.7	5.4	211
Central Sulawesi	22.0	10.8	20.4	10.4	161
Southeast Sulawesi	27.0	9.2	22.0	8.0	111
Maluku	17.6	4.3	15.4	4.3	166
Irian Jaya	31.1	10.5	26.1	9.7	162
Total	26.9	9.0	23.7	8.2	15,433

Treatment of fever varies little by the sex of the children. High-birth-order children with fever are more likely to get no treatment than low-birth-order children (25 percent for seventh or higher order, compared with 14 percent for first children). Children of mothers with no education are the least likely to be treated for fever.

Table 12.2.1 Prevalence and treatment of acute respiratory infection: background characteristics

Among children under five years of age, the percentage who were ill with a cough accompanied by rapid breathing during the two weeks preceding the survey, and the percent distribution of these children by type of treatment received, according to background characteristics, Indonesia 1997

The prevalence of any fever is high (30 percent or higher) in West Sumatra, West Nusa Tenggara, North Sulawesi, East Nusa Tenggara, Central Kalimantan, and Irian Jaya (Table 12.3.2). The prevalence of fever only is highest in North Sulawesi (11 percent).

Children in the Outer Java-Bali regions are less likely to receive treatment for fever than those in Java-Bali—13 percent of children in Java-Bali received no treatment, compared with 18-19 percent of children in the Outer Java-Bali regions. One in six children in Central Sulawesi and Maluku received

treatment from a traditional healer.

Table 12.2.2 Prevalence and treatment of acute respiratory infection: region and province

12.3 Diarrheal Disease

Diarrheal diseases continue to be a public health problem in Indonesia. A Diarrhea Control Program has been instituted by improving environmental sanitation to reduce the incidence of diarrhea, and by improving treatment facilities in the hospitals, health centers, and health posts to reduce case fatality rates.

of care. Oral rehydration centers have been established in health centers and health posts. Education about the use of oral rehydration therapy (ORT) for treatment of diarrhea has been introduced through the mass media, especially television.

Table 12.3.1 Prevalence and treatment of fever: background characteristics

Figure 12.2
Treatment of Childhood Diseases

Prevalence of Diarrhea

In the 1997 IDHS, mothers with children under five years of age were asked if their children had had diarrhea at any time in the two weeks preceding the survey and whether they had diarrhea in the last 24 hours. The survey was conducted between September and December 1997, which was the end of the dry season and the beginning of the rainy season, when the incidence of diarrhea is expected to decline.

Table 12.4.1 shows that 10 percent of children were reported to have had diarrhea in the two weeks preceding the survey, including 2 percent who had diarrhea in the last 24 hours. The prevalence of diarrhea with blood in stools is less than 1 percent.

The prevalence of diarrhea in the two-week period and in the last 24 hours preceding the survey is highest among children age 6-11 months. Diarrhea prevalence varies little by the child's sex, birth order, and residence. Children of mothers who have had no education and children of mothers with some secondary education have slightly lower prevalence of diarrhea than other children. There are some variations in the prevalence of bloody diarrhea.

Table 12.4.1 also presents the prevalence of persistent diarrhea, which is defined as diarrhea in the preceding two weeks that has lasted for at least 14 days and still persists in the 24 hours before the survey. Overall, very few children have persistent diarrhea, and there is little variation by background characteristics.

As shown in Table 12.4.2, the two-week diarrhea prevalence varies slightly by region—12 percent in the Outer Java-Bali II and 10 percent in the Outer Java-Bali I and Java-Bali regions. Central Kalimantan shows the highest prevalence of diarrhea in the two-week period and in the 24 hours preceding the survey (20 and 6 percent, respectively).

Table 12.3.2 Prevalence and treatment of fever: region and province

³ Pharmacy or shop

Duration and Incidence of Diarrhea

The average duration of a diarrheal episode is calculated from the durations for all children who had diarrhea in the preceding two weeks, excluding those who had diarrhea in the last 24 hours (i.e., terminated episodes only). The results, presented in Tables 12.5.1 and 12.5.2, indicated that the average duration of a diarrheal episode is 3.1 days.

Table 12.4.1 Prevalence of diarrhea: background characteristics

¹ Includes diarrhea in the last 24 hours

² Includes diarrhea with blood

³ Diarrhea in the last 24 hours and diarrhea in the preceding two weeks that lasted for at least 14 days

There is little difference in the duration of diarrheal episodes by background characteristics. However, the mean duration of diarrhea is slightly longer among children under age 6-12 months and children in the rural areas than that among other children. There are negligible differences in the mean duration of diarrhea by mother's education.

Table 12.4.2 Prevalence of diarrhea: region and province

Note: Figures in parentheses are based on 250-499 births. An asterisk indicates that a figure is based on fewer than 250 births and has been suppressed.

The two-week diarrheal incidence is defined as the percentage of children having a diarrheal episode that started in the preceding two weeks. It is estimated from the relationship of prevalence to incidence as follows:

$$\begin{aligned}
 I_{1-14} &= P_{2-14} \times 14 / (13 + D), \text{ incidence in the 14 days preceding the survey} \\
 P_{2-14} &= \text{prevalence in the 2-14 days preceding the survey} \\
 D &= \text{average duration of a diarrheal episode in the 2-14 days preceding the survey}
 \end{aligned}$$

The two-week incidence of diarrhea is 7 percent, which is slightly lower than that recorded in the 1991 IDHS and 1994 IDHS (11 and 8 percent). Diarrhea incidence is higher among children age 6-23 months than among infants under 6 months, perhaps in part because the latter is influenced by the much higher proportion of children with supplementary feeding (Table 13.3). Diarrhea incidence tends to decrease among older children and declined to 4 percent among children 48-59 months.

The variation in diarrhea incidence across residence and region and among subgroups of children was smaller in 1997 than that recorded in the 1994 IDHS.

The mean duration of diarrhea that terminated in the 24 hours preceding the survey was 3.1 days or longer in North Sumatra, West Kalimantan, and Bengkulu (Table 12.5.2). The incidence of diarrhea in the two weeks preceding the survey was highest in Bengkulu, East Nusa Tenggara, and Central Kalimantan (11 days).

Knowledge of Diarrhea Care

The recommended treatment for diarrhea is oral rehydration therapy (ORT), including a solution prepared from ORS packets (prepackaged oral rehydration salts) and increased fluids. In Indonesia ORT is promoted through health education and mass media campaigns. A mother is classified as knowing about ORT if she reported ever having heard about Oralit—the brand of ORS most commonly used—or has seen an ORS packet.

Tables 12.6.1 and 12.6.2 show that the vast majority (94 percent) of mothers have heard about or seen ORS packets. Knowledge of ORT is greater in the urban areas and among more educated mothers. Virtually all women with some secondary education (98 percent) have heard of Oralit or seen ORS packets, compared to only 83 percent of mothers with no education. The percentage of mothers with knowledge of ORS packets in the Outer Java-Bali II regions is slightly lower than in the other two regions (91 percent, compared with 94 percent or higher). While in most provinces virtually all mothers have heard of or seen ORS packets, the proportion in Jambi and Maluku is 87 percent or less (Table 12.6.2).

Information was collected on mother's knowledge of appropriate feeding practices during diarrhea. Table 12.6.1 shows that 66 percent of mothers reported they would give increased fluids, 21 percent would give the same amount of fluids, and 11 percent would give less fluids. Young mothers and those with no education are less likely to give increased fluids to their children during a diarrheal episode.

Mothers are equally divided about feeding their children solid food during diarrhea; one in three said she would give less food to children with diarrhea, one-third would give the same amount of food, and almost one-third would give more food to their children during a diarrheal episode. Urban mothers are more likely than rural mothers to give more food to their children during a diarrheal episode. There is little difference in mothers' knowledge of appropriate feeding practices during diarrhea by age. Mothers with some secondary education are more likely to give more food to their children during diarrhea than mothers with less education.

In DKI Jakarta and DI Yogyakarta, 82-91 percent of mothers would give more fluids to their children during diarrhea, and only 2-3 percent would reduce it (see Table 12.6.2). In West Java, where outbreaks of diarrheal disease occur frequently, 70 percent of mothers would increase the children's fluid intake and 7 percent would reduce it during a diarrheal episode. More than half of mothers in West Kalimantan, Bengkulu, and Central Kalimantan, where the prevalence and incidence of diarrhea are also high, would increase fluid intake, and 8-14 percent would reduce it during diarrhea.

Table 12.6.1 Knowledge of diarrhea care: background characteristics

ORT = Oral rehydration therapy

¹ Respondent had heard of or seen *Oralit* packets (i.e., packets of oral rehydration salts commonly used to treat diarrhea in Indonesia).

ORT = Oral rehydration therapy

¹ Respondent had heard of or seen *Oralit* packets (i.e., packets of oral rehydration salts commonly used to treat diarrhea in Indonesia).

Although 94 percent of mothers have heard about or seen ORS packets, only 68 percent of mothers have ever used ORS packets to treat diarrhea. Young mothers, mothers in the rural areas, and mothers with no education are less likely to have ever used ORS than other mothers (Table 12.7.1).

Mothers in Outer Java-Bali II region are slightly less likely to have ever used ORS packets than mothers in the other two regions (64 percent, compared with 68 percent or higher). The experience in using ORS packets for children with diarrhea varies substantially across provinces, from 85 percent in West Nusa Tenggara to 40 percent or less in East Timor and Maluku (Table 12.7.2).

ORT = Oral rehydration therapy

¹ Respondent had heard of or seen *Oralit* packets (i.e., packets of oral rehydration salts commonly used to treat diarrhea in Indonesia).

Diarrhea Treatment

Table 12.8.1 and Figure 12.2 shows that 54 percent of children who had diarrhea in the two weeks preceding the survey were taken to a health facility or provider, 21 percent received self-treatment, and 23 percent were not treated at all.

Treatment of diarrhea varies by the child's age. Infants under 6 months with diarrhea are less likely to be treated, either by being taken to a health facility or by being given self-treatment than older children.

Table 12.7.1 Knowledge and ever use of ORS packets: background characteristics

ORS = Oral rehydration salts			

While 28 percent of infants under 6 months were taken to a health facility and 6 percent received self-treatment; the corresponding percentages for older children are 51 percent or higher and 12-30 percent, respectively.

First- and seventh-order children who had diarrhea are more likely to be taken to a health facility than other children (60 percent or more, compared with 47 to 52 percent for lower order children). Rural mothers are slightly more likely to take their children with diarrhea to a health facility than urban mothers. On the other hand, urban mothers are more likely to give their children treatment at home during diarrhea than rural mothers.

Treatment of children with diarrhea varies by mother's education. Children of mothers with no education are less likely to be taken to a health facility and much more likely to receive treatment from a traditional healer. For example, among children with diarrhea whose mothers had no education, 40 percent were taken to a health facility for treatment, 15 percent were taken to traditional healer, and 25 percent had

no treatment. Among children of women who had some secondary education, 59 percent were taken to a health facility, 24 percent received self-treatment, and 17 percent received no treatment (Table 12.8.1).

ORS = Oral rehydration salts			

While there is only a slight difference in diarrhea treatment according to region, some provincial variation exists (Table 12.8.2). In certain provinces—West Java, South Kalimantan, Riau, Bengkulu, East Kalimantan, and Central Sulawesi—less than half of children with diarrhea are taken to a health facility; they are more likely to receive self-treatment or no treatment at all.

¹ Includes hospital, health center, health post, private clinic, doctor, nurse, midwife, village delivery post, and health cadre

² Pharmacy or shop

Children who have diarrhea may be given a solution (prepared from ORS packets²), homemade fluids, other treatments, increased fluids, or a combination of these treatments. Although more than 90

² ORS (oral rehydration salts) packets contain a commercially prepared mixture of salts, sugars, and complex carbohydrates that when mixed correctly with water is an effective treatment for diarrhea in children. The brand of ORS most commonly used in Indonesia is *Oralit*.

percent of mothers reported that they had heard of or seen ORS packets, in practice, only 48 percent of children with diarrhea were treated with ORS (Table 12.9.1). Overall, 40 percent of children with diarrhea were given other fluids, 70 percent received either ORS or other fluids, and 78 percent were given some other treatment, including treatments obtained from a pharmacy. A majority of children with diarrhea were given ORS or increased fluids (57 percent). One in 12 children with diarrhea received no treatment at all, i.e., neither given ORS or increased fluids, nor taken to a health facility or given self-treatment.

ORS = Oral rehydration salts								

Infants under age 6 months with diarrhea are less likely than older children to be given ORS or increased fluids. In fact, they are less likely to be treated at all, probably because most are still being breastfed. The provision of ORS and increased fluids varies little according to the sex of the child, the birth order, urban/rural residence, and mother's education, although children whose mothers are more educated are more likely to be given increased fluids than children of less educated mothers. Treatment of diarrhea increases with mother's education; children whose mothers have some secondary education are the most likely to be treated.

Table 12.9.2 Treatment of diarrhea: region and province

ORS = Oral rehydration salts

Note: Figures in parentheses are based on 25-49 births. An asterisk indicates that a figure is based on fewer than 25 births and has been suppressed.

Children with diarrhea in Java-Bali are less likely to be given ORS than children in the Outer Java-Bali regions (43 percent, compared with 52 percent or higher). The use of ORS varies substantially across provinces, from 77 percent in East Timor to 38 percent in West Java (Table 12.9.2). Although use of ORS is low (less than 40 percent) in the provinces of DKI Jakarta and West Java, most children with diarrhea received increased fluids and some form of other treatment. The percentage of children with diarrhea who received no treatment ranges from less than 2 percent in South Sumatra, West Kalimantan, and East Nusa Tenggara to 15 percent or higher in Lampung and Southeast Sulawesi.

Feeding Practices During Diarrhea

Diarrheal episodes are frequently accompanied by vomiting, which makes feeding difficult because the child frequently refuses food. Table 12.10 and Figure 12.3 show that 20 percent of children with diarrhea received an increased amount of solid food, and 57 percent received increased fluids. For children who were still breastfed for whom information was available, few received less or no breast milk during diarrhea, while three in four received the same amount, and a small proportion were given more breast milk.

CHAPTER 13

INFANT FEEDING

Breastfeeding is of utmost importance to the health and survival of infants. In Indonesia, exclusive breastfeeding is recommended for infants under 4 months of age; the introduction of supplementary food is recommended at age 4 to 6 months.

13.1 Prevalence of Breastfeeding and Supplementation

Table 13.1.1 shows that virtually all children born in the five years preceding the survey were breastfed for at least some time (96 percent). There are negligible differences in the proportion of children ever breastfed by background characteristics.

Table 13.1.1 Initial breastfeeding: background characteristics

Total	96.3	8.3	52.7	16,217

Note: Includes one child with missing information on place of delivery.

¹ Includes children who started breastfeeding within one hour of birth.

In Indonesia, 8 percent of newborns are breastfed within the first hour, and more than half (53 percent) start within the first day. Differences between subgroups of children in the percentage receiving breast milk during the first day are small. Mothers in Java-Bali and Outer Java-Bali II regions are more likely to start giving breast milk to their babies earlier than women in Outer Java-Bali I region. The percentage of children breastfed during the first day of life declines as mother's level of education increases; 61 percent of children whose mothers had no education began breastfeeding within the first day, compared with 53 percent of those whose mothers attended secondary school.

It is interesting to note that the proportion of first-day breastfeeding is lowest among women who were assisted by a medical professional at delivery (51 percent) and highest (67 percent) among women who had no assistance at delivery or were assisted by other people, e.g., friends and relatives. There is no difference in first-day breastfeeding among children born at home or at health facilities (both 53 percent).

The proportion of children receiving breast milk in the first hour of life ranges from less than 3 percent in Jambi and East Nusa Tenggara to 27 percent in Central Kalimantan (Table 13.1.2). The proportion who start to breastfeed in the first day of life varies from 35 percent in Central Sulawesi to 78 percent in Bali.

Mothers who were currently breastfeeding were asked if they had given various types of liquids or solid foods to the child in the last 24 hours (Table 13.2 and Figure 13.1). Children are classified as being exclusively breastfed if they receive breast milk only in the last 24 hours. Full breastfeeding is defined as receiving plain water only in addition to breast milk. Virtually all infants under 7 months were breastfed (92-97 percent). The prevalence of breastfeeding declines to 89 percent at age 12-13 months and to 59 percent at age 22-23 months.

³ May receive other liquids or other milk

Figure 13.1
Distribution of Children by Breastfeeding
(BF) Status, According to Age

IDHS97

In general, more than half of infants under 4 months were exclusively breastfed (52 percent). The prevalence of exclusive breastfeeding declines from 62 percent for infants age under 2 months, to 44 percent among those age 2-3 months, to 24 percent among children 4-5 months. A small percentage of infants under 6 months of age were given plain water only in addition to breast milk.

Among currently breastfed children, some were given supplementary liquids such as plain water, water with sugar or honey, fruit juice, tea, starch water, and other types of milk or supplementary foods such as meat, fish, eggs, liver, mashed food, or porridge. Supplementary feeding is introduced very early in infancy; 35 percent of infants under 2 months of age were given supplements consisting of plain water (3 percent), other liquids (4 percent), other milk (11 percent), and solid or mushy foods (17 percent). The proportion of infants receiving supplementary feeding increases rapidly with age. Solid foods are given to 37 percent of infants at age 2-3 months, 62 percent of those age 4-5 months, and 78 percent of infants age 6-7 months.

Table 13.3 presents data on types of food given to breastfeeding children under 3 years of age, the use of a bottle with a nipple in feeding these children, and the use of a pacifier. With regard to the mode of feeding, 10 percent of infants under 2 months were fed using a bottle with a nipple. The proportion increases to 12 percent among infants age 8-9 months.

Beside bottle feeding with a nipple or teat, pacifiers are frequently used to satisfy the infant's sucking demand. Among currently breastfed children, the use of pacifiers decreases with age, from about 8 percent or higher among infants under 5 months, to 5 percent among those 10-11 months, and to less than 4 percent among children 14 months or older (Table 13.3).

Table 13.3 Type of foods received

Percent of breastfeeding children under three years who received various types of food in the 24 hours preceding the interview, and the percentage using a bottle with a nipple, and using a pacifier, by child's age in months, Indonesia 1997

13.2 Duration of Breastfeeding

In Indonesia, breastfeeding is not only universal but also relatively long. The median duration of breastfeeding is estimated at 23.9 months (see Table 13.4.1 and Figure 13.2). Children who live in rural areas are breastfed longer than children in urban areas (25 months compared with 22 months). Children in Java-Bali, those born to mothers with less education, and those whose births were assisted by a traditional birth attendant are breastfed longer than other children. The median duration of breastfeeding in Java-Bali is 26 months, compared with 22 months in Outer Java-Bali I and 23 months in Outer Java-Bali II. Children born to mothers with no education are breastfed for almost 7 months longer than those born to mothers with secondary education. Children whose births were assisted by a traditional birth attendant are breastfed for more than 3 months longer than children whose births were assisted by a medical professional, or other person, or no one.

Supplements to breastfeeding are not recommended until the infant reaches 4 months of age. However, the median durations of exclusive and full breastfeeding are 1.7 months and 1.9 months, respectively, which suggests that food supplements are introduced at an earlier age than recommended. The duration of exclusive and full breastfeeding in the Outer Java-Bali regions are longer than in Java-Bali. For example, in Outer Java-Bali II the median duration of full breastfeeding is 2.7 months, compared with 1.7 months in Java-Bali.

Table 13.4.1 Median duration and frequency of breastfeeding: background characteristics

Median durations of any breastfeeding, exclusive breastfeeding, and full breastfeeding among children under three years, and the percentage of children under six months of age who were breastfed six or more times in the 24 hours preceding the interview, by background characteristics, Indonesia 1997

Figure 13.2
Median Duration of Any Breastfeeding

IDHS97

It is recommended that infants under 6 months of age be breastfed frequently. Table 13.4.1 shows that 92 percent of infants under 6 months of age were breastfed six or more times in the 24 hours prior to the survey. Differences according to background characteristics are minimal.

Breastfeeding duration ranges from 18 months in North Sulawesi to 29 months in West Kalimantan (Table 13.4.2). In some provinces (East Java, Dista Aceh, North Sumatra, and West Kalimantan), the median duration of exclusive and full breastfeeding is less than 1 month.

The percentage of infants who were breastfed frequently shows little variation according to region. In the Java-Bali region, infants in DKI Jakarta are less likely than infants in other provinces to be given breast milk frequently (81 percent compared with 89 percent or higher in other provinces). In the Outer Java-Bali regions, West Sumatra and South Sulawesi have the lowest proportions of infants receiving breast milk more than six times during the 24 hours prior to the survey (less than 85 percent).

CHAPTER 14

KNOWLEDGE OF AIDS

In 1986, the Ministry of Health of Indonesia established a coordination board for control of the disease caused by the human immunodeficiency virus (HIV), i.e., acquired immunodeficiency syndrome (AIDS). Since then, various efforts for preventing transmission of the disease have been made, such as public health education through media and nongovernmental organization activities.

In the 1997 Demographic and Health Survey (IDHS), ever-married women age 15-49 years were asked whether they had ever heard of AIDS and, if so, what were their sources of information concerning prevention and treatment of the disease, and what were their personal perceptions about the risk of getting the disease. Currently married women were asked about any changes they had made in sexual behavior to avoid getting AIDS and whether they and their husbands were currently using condoms.

14.1 Source of Information About AIDS

Table 14.1.1 shows the percentage of ever-married women who have heard of AIDS by source of information, according to background characteristics. In this survey, a respondent may report having heard about AIDS from more than one source. Overall, 51 percent of ever-married women have heard of AIDS: 47 percent of all ever-married women received information about AIDS from television; 18 percent received it from radio broadcasts, 15 percent from newspaper or magazines, and 11 percent from friends or relatives. Similar patterns are found for almost all subgroups of women.

The percentage of women who have heard of AIDS varies by age and follows an inverted U-shaped pattern, i.e., low for the youngest age group and women age 30 years and over, and high among women age 20 to 29 years. The percentage of women who have heard of AIDS is higher among currently married women (52 percent) than among those who are widowed (35 percent) or divorced (44 percent).

Urban women are almost twice as likely to have heard about AIDS as women in the rural areas (77 versus 42 percent). This pattern occurs in all regions. Knowledge of AIDS is slightly higher (54 percent) in Outer Java-Bali I than in other regions. Knowledge of AIDS increases with women's level of education, from only 14 percent for women with no education to 88 percent for women with some secondary education (see Figure 14.1).

The percentage of women who have heard about AIDS varies by province, from 25 percent in East Timor and East Nusa Tenggara to 90 percent in DKI Jakarta (Table 14.1.2.). The role of television broadcasting in informing the public about AIDS is notable in DKI Jakarta (87 percent) and North Sulawesi and East Kalimantan (70 percent). Friends and relatives are an important source of information about AIDS for more than 20 percent of women in DKI Jakarta, South Sumatra, and North Sulawesi.

14.2 Knowledge of Ways to Prevent AIDS

One in five women who have heard of AIDS believes there is no way to avoid getting the disease (Table 14.2.1). Those who said that AIDS is preventable could state more than one way to avoid it. Among these women, the most common response is that AIDS is preventable by having sex with only one partner (29 percent) or by avoiding having sex with prostitutes (24 percent). This belief is found among almost all subgroups, and particularly among urban and better educated women. A small percentage of women cited

avoiding having sex with homosexuals, avoiding blood transfusions, and avoiding injections (each about 3 to 6 percent) as ways to avoid getting AIDS. Four percent of women said using condoms during intercourse could prevent AIDS.

Table 14.1.1 Knowledge of AIDS and sources of AIDS information: background characteristics

Total	51.4	18.2	46.7	15.4	1.6	3.1	0.4	0.4	11.4	2.0	1.5	28,810	1.0
Ever-married women who have heard of AIDS	100.0	35.4	90.9	30.0	3.0	6.1	0.8	0.8	22.2	3.8	2.9	14,835	2.0

The percentage of women who believe there is no way to avoid AIDS varies little by age group or marital status; however, the percentage is slightly higher among women with no education. Rural women are more likely than urban women to say that there is no way to avoid AIDS (22 percent, compared with 15 percent), and women in the Outer Java-Bali regions are more likely than women in Java-Bali to say that AIDS is unavoidable (27 and 30 percent, compared with 13 percent).

Figure 14.1
Knowledge of AIDS Among
Ever-Married Women

IDHS97

Knowledge of ways to prevent AIDS varies by province. The percentage of women who say that AIDS is not preventable varies: 7 percent in DKI Jakarta, 49 percent in East Nusa Tenggara, 51 percent in Jambi, and 78 percent in East Timor (Table 14.2.2). The percentage of women who say that one way of avoiding AIDS is by having only one sexual partner varies from 6 percent in East Timor to 45 percent in DKI Jakarta. The percentage of women who cite avoiding having sex with prostitutes varies from 3 percent in East Timor to over 35 percent in DKI Jakarta and West Sumatra.

14.3 Women's Perceptions of the Risk of Getting AIDS

Fifty-six percent of women who have heard of AIDS believe that the disease cannot be cured: 25 percent say that it is curable, and 19 percent do not know whether AIDS is curable (Table 14.3.1). The proportion who say that AIDS cannot be cured varies; it is lowest among women age 15-19 years (49 percent) and women with no education (47 percent) and highest among women in the urban areas, especially in Outer Java-Bali II (65 percent) and among women who have had some secondary education (63 percent).

Seven in ten women believe that they have no chance of contracting AIDS, 8 percent say their chance is small, and 10 percent say that they have a moderate chance. A negligible percentage believe themselves to be at great risk of contracting AIDS. Differences in the perception of AIDS risks between subgroups are small.

Although the percentage of women who believe that AIDS cannot be cured varies slightly by region, there are significant differences by province, ranging from 48 percent in North Sumatra to 82 percent in East Timor (Table 14.3.2). The percentage of women who consider themselves at no risk of getting AIDS varies from 52 percent in DKI Jakarta to 87 percent or higher in North Sulawesi, East Timor, and Southeast Sulawesi.

14.4 AIDS Prevention Behavior

Currently married women who had heard of AIDS were asked if they had changed their sexual behavior to avoid getting AIDS (Table 14.4.1). Virtually all of these women (94 percent) reported that they had not changed their sexual behavior after hearing about the disease. There is little variation by background characteristics or by province. Women in DKI Jakarta are the most likely to change their sexual behavior (Table 14.4.2).

Table 14.2.1 Knowledge of ways to avoid AIDS: background characteristics

¹ Includes avoiding kissing, mosquito bites, and "other."

14.5 Knowledge and Use of Condoms

The great majority (86 percent) of currently married women who have heard of AIDS also know about condoms (Table 14.5.1). The proportions are smaller for women under age 20 (68 percent) and for women who have no education (70 percent). Knowledge of condoms among women who have heard of AIDS increases with level of education. Urban women are slightly more likely than rural women to know about condoms (93 percent compared with 81 percent).

¹ Includes avoiding kissing, mosquito bites, and "other."

Twenty-nine percent of women who have heard of AIDS and know about condoms say they would go to a government source for condoms; 13 percent would go to a private source such as a private hospital, a family planning clinic, or a doctor or a midwife; and 29 percent would go to a pharmacy. Public sources are more popular among older women, rural women, and women in the Outer Java-Bali II region. Pharmacies are a common source among women age 25 years and older, urban women, women living in Java-Bali, and better educated women.

Overall, only 7 percent of currently married women who know of AIDS have used condoms (Table 14.5.1). The use rate increases with age and education. Urban women are more than twice as likely to have used condoms as rural women (11 percent compared with 4 percent). Women who say they have a small or moderate risk of getting AIDS are much more likely to have used condoms than women who say that they

have a great risk (10 percent compared with 5 percent). The percentage of women who have used condoms is slightly higher among women who did not change their sexual behavior to avoid AIDS (7 percent) than among those who did change their sexual behavior (5 percent).

Table 14.3.1 Perception of the risk of getting AIDS: background characteristics

Percent distribution of ever-married women who have heard of AIDS by whether they believe AIDS can be cured, and by their perception of the risk of getting AIDS, according to background characteristics, Indonesia 1997

The percentage of women who have heard of AIDS and know about condoms varies from 44 percent in East Timor to almost 100 percent in DI Yogyakarta (Table 14.5.2). Among these women, 71 percent in DKI Jakarta would go to pharmacies for condoms, while in South Sulawesi, Central Sulawesi, Maluku, and Irian Jaya over 60 percent would go to a government source. The use of condoms among currently married women who know about AIDS ranges from 1 percent in East Timor to 21 percent in DI Yogyakarta.

Table 14.3.2 Perception of the risk of getting AIDS: region and province

APPENDIX A

SURVEY DESIGN

APPENDIX A

SURVEY DESIGN

The main objective of the 1997 Indonesia Demographic and Health Survey (IDHS) was to provide information on fertility, family planning, maternal and child health, and maternal and child mortality that can be used by program managers and policy makers to evaluate and improve existing programs. The survey is a follow-on to the 1987 National Indonesia Contraceptive Prevalence Survey (NICPS), the 1991 IDHS and the 1994 IDHS. All of these surveys were carried out by the Central Bureau of Statistics (CBS).

A.1 Sample Design and Implementation

Indonesia is divided into 27 provinces. For the implementation of its family planning program, the National Family Planning Coordinating Board (NFPCB) has divided these provinces into three regions as follows:

Java-Bali: DKI Jakarta, West Java, Central Java, DI Yogyakarta, East Java, and Bali
Outer Java-Bali I: Dista Aceh, North Sumatra, West Sumatra, South Sumatra, Lampung, West Nusa Tenggara, West Kalimantan, South Kalimantan, North Sulawesi, and South Sulawesi
Outer Java-Bali II: Riau, Jambi, Bengkulu, East Nusa Tenggara, East Timor, Central Kalimantan, East Kalimantan, Central Sulawesi, Southeast Sulawesi, Maluku, and Irian Jaya

The 1990 Population Census of Indonesia shows that Java-Bali accounts for 62 percent of the national population, Outer Java-Bali I accounts for 27 percent, and Outer Java-Bali II accounts for 11 percent. The sample for the 1997 IDHS was designed to produce reliable estimates of fertility, contraceptive prevalence and other important variables for each of the provinces and urban and rural areas of the three regions.

In order to meet this objective, between 1,650 and 2,050 households were selected in each of the provinces in Java-Bali, 1,250 to 1,500 households in the ten provinces in Outer Java-Bali I, and 1,000 to 1,250 households in each of the provinces in Outer Java-Bali II, for a total of 35,500 households. With an average of 0.8 ever-married women 15-49 per household, the sample was expected to yield approximately 28,000 women eligible for the individual interview.

The 1997 IDHS sample is a replication of the 1994 IDHS sample. The sample is stratified by province and by urban and rural domain within each province. The sample was selected in three stages. In the first stage, census enumeration areas (EAs) were selected systematically with probability proportional to population size. In each EA, segments of approximately 70 contiguous households with clear boundaries were formed, and only one segment was selected with a probability proportional to size. In the third stage, 25 households were selected from each segment using a systematic sampling. A complete listing of all households in the selected segments was carried out prior to the selection of households.

Since the sample was designed to produce estimates at the provincial level, the households selected at the provincial level did not constitute a proportional representation at the national level. Specifically, households in Outer Java-Bali II were oversampled. The results presented in this report are based on data that were weighted to take account of differential sampling probabilities and nonresponse at both the household and individual levels. The weights are used to produce estimates that are representative at the appropriate level of aggregation (e.g., provincial, regional, and national).

Results of the sample implementation by region and by urban-rural residence as well as by province are shown in Tables A.1 and A.2. As shown in Table A.1, 35,362 households were selected for the 1997 IDHS. Of these, 97 percent were successfully interviewed, 1 percent were not interviewed because there was no competent respondent, 1 percent were found to be vacant, and 1 percent were away during the survey fieldworkers' visit. Other reasons for not interviewing include no competent respondent in the household or the dwelling had been destroyed. The overall household response rate is 99 percent (see Table A.1 for definition). The level of successful household interviews ranges from less than 94 percent in Central Kalimantan and Southeast Sulawesi to 100 percent in East Timor. The response rates are slightly higher in rural than in urban areas.

Table A.2 presents the survey coverage for the individual interview by region and type of residence. The eligible woman response rate for the 1997 IDHS is 98 percent. The response rates for eligible women are generally lower than household response rates, but range from 95 percent in Bengkulu and Jambi to 100 percent in East Timor. There is little variation by urban-rural residence. The overall response rate--which is the product of the household response rate and the eligible woman response rate--is 97 percent.

A.2 Pretest

Since all of the survey instruments except the family welfare questionnaire were the same as those used in the 1994 IDHS, the pretest was focused on this questionnaire. Six male and four female CBS staff participated in the pretest. Two of the female staff were from the West Java Province Statistics Office (PSO). The pretest training was conducted by CBS staff for three days in June 1997, followed by the data collection, which lasted for three days. The pretest took place in a location outside Jakarta, the capital.

For the pretest fieldwork, a total of 100 households, 121 family welfare and 44 individual women questionnaires were completed. Problems encountered during the pretest training and fieldwork were discussed among the collaborating agencies: NFPCB, CBS, and the Ministry of Health. Based on these discussions, the family welfare questionnaire was finalized. While the household expenditure schedule is a part of the Household Questionnaire, it was decided that it would be administered after the interview with the eligible women in the household had been completed. The family welfare questionnaire would be asked last.

A.3 Field Staff Training

Training of the survey field staff for the main survey was preceded by a course for prospective instructors of field workers, persons who were responsible for the training centers, and the data processing staff. This training was held in August 1997 in Bogor. CBS staff who participated in previous DHS surveys served as trainers.

Training for the main survey took place in nine locations spread throughout the country: Medan (North Sumatra), Palembang (South Sumatra), Jakarta (DKI Jakarta), Salatiga (Central Java), Malang (East Java), Kupang (East Nusa Tenggara), Balikpapan (East Kalimantan), and Ujung Pandang (South Sulawesi). The training lasted for 16 days. Due to variability in the availability of funds, the training did not take place simultaneously in all training centers. The training was patterned after past IDHS experiences and followed the model DHS training guidelines. Procedures for locating the sample households, conducting an interview, and filling out the forms, as well as tests, mock interviews and field practice were included in the training.

Table A.1 Sample implementation: results of the household interview

Percent distribution of households in the DHS sample by results of the household interview, and household response rates, according to region, province, and urban-rural residence, Indonesia 1997

¹The eligible woman response rate (EWRR) is calculated as:

$$\frac{C}{C + NH + PP + R + PC + I + O}$$

²The overall response rate (ORR) is calculated as: HRR × EWRR.

A.4 Fieldwork

The 1997 IDHS data were collected by 284 interviewers, 86 field editors and 86 supervisors. Each of the 86 teams consisted of two to four interviewers, one field editor and one supervisor. As in previous DHS surveys, the number of teams in each province was determined by the number of segments selected in the respective province and their distribution throughout the area. Due to the sensitive nature of some questions asked in the survey, all interviewers and field editors were female. However, for logistical and security reasons, male supervisors were used. Most of the survey fieldworkers were CBS staff at the province or regency/municipality level.

The teams completed work in each segment before moving to the next segment. Generally, the teams were responsible for arranging transportation between sample areas. However, in some areas, local statistics offices provided transportation. In each province, the PSO Director was responsible for the implementation of the survey in his/her province, while the Chief of the Population and Social Statistics Division was assigned as the Technical Coordinator. During the course of data collection, PSO and CBS staff visited the field periodically to monitor the progress of the fieldwork. The main survey fieldwork began on September 1, 1997 in South Sumatra. The last segment was completed on December 31, 1997.

A.5 Data Processing

The first stage of data editing was carried out by the field editors who checked the completed questionnaires for thoroughness and accuracy. Field supervisors then further examined the questionnaires. In many instances, the teams sent the questionnaires to CBS through the regency/municipality statistics offices. In these cases, no checking was done by the PSO. In other cases, Technical Coordinators are responsible for reviewing the completeness of the forms. At CBS, the questionnaires underwent another round of editing, primarily for completeness and coding of responses to open-ended questions.

The data were processed using microcomputers and the DHS computer program, ISSA (Integrated System for Survey Analysis). Data entry and office editing were initiated immediately after fieldwork began. Simple range and skip errors were corrected at the data entry stage. Data processing was completed by February 1998, and the preliminary report of the survey was published in April 1998.

APPENDIX B

ESTIMATES OF SAMPLING ERRORS

The estimates from a sample survey are affected by two types of errors: (1) nonsampling errors, and (2) sampling errors. Nonsampling errors are the results of mistakes made in implementing data collection and data processing, such as failure to locate and interview the correct household, misunderstanding of the questions on the part of either the interviewer or the respondent, and data entry errors. Although numerous efforts were made during the implementation of the 1997 IDHS to minimize this type of error, nonsampling errors are impossible to avoid and difficult to evaluate statistically.

Sampling errors, on the other hand, can be evaluated statistically. The sample of respondents selected in the 1997 IDHS is only one of many samples that could have been selected from the same population, using the same design and expected size. Each of these samples would yield results that differ somewhat from the results of the actual sample selected. Sampling errors are a measure of the variability between all possible samples. Although the degree of variability is not known exactly, it can be estimated from the survey results.

A sampling error is usually measured in terms of the *standard error* for a particular statistic (mean, percentage, etc.), which is the square root of the variance. The standard error can be used to calculate confidence intervals within which the true value for the population can reasonably be assumed to fall. For example, for any given statistic calculated from a sample survey, the value of that statistic will fall within a range of plus or minus two times the standard error of that statistic in 95 percent of all possible samples of identical size and design.

If the sample of respondents had been selected as a simple random sample, it would have been possible to use straightforward formulas for calculating sampling errors. However, the 1997 IDHS sample is the result of a multi-stage stratified design, and, consequently, it was necessary to use more complex formulae. The computer software used to calculate sampling errors for the 1997 IDHS is the ISSA Sampling Error Module. This module used the Taylor linearization method of variance estimation for survey estimates that are means or proportions. The Jackknife repeated replication method is used for variance estimation of more complex statistics such as fertility and mortality rates.

The Taylor linearization method treats any percentage or average as a ratio estimate, $r = y/x$, where y represents the total sample value for variable y , and x represents the total number of cases in the group or subgroup under consideration. The variance of r is computed using the formula given below, with the standard error being the square root of the variance:

$$var_T(r) = \frac{1-f}{x^2} \sum_{h=1}^H \left[\frac{m_h}{m_h-1} \left(\sum_{i=1}^{m_h} z_{hi}^2 - \frac{z_h^2}{m_h} \right) \right]$$

in which

$$z_{hi} = y_{hi} - r \cdot x_{hi}, \text{ and } z_h = y_h - r \cdot x_h$$

where h represents the stratum which varies from 1 to H ,
 m_h is the total number of clusters selected in the h^{th} stratum,
 y_{hi} is the weighted sum of the values of variable y in the i^{th} cluster in the h^{th} stratum,

x_{hi} is the weighted sum of the number of cases in the i^{th} cluster in the h^{th} stratum, and
 f is the overall sampling fraction, which is so small that it is ignored.

The Jackknife repeated replication method derives estimates of complex rates from each of several replications of the parent sample, and calculates standard errors for these estimates using simple formulae. Each replication considers *all but one* clusters in the calculation of the estimates. Pseudo-independent replications are thus created. In the 1997 IDHS, there were 1,413 non-empty clusters. Hence, 1,413 replications were created. The variance of a rate r is calculated as follows:

$$\text{var}_j(r) = \frac{1}{k(k-1)} \sum_{i=1}^k (r_i - r)^2$$

in which

$$r_i = kr - (k-1)r_{(i)}$$

where r is the estimate computed from the full sample of 1,413 clusters,
 $r_{(i)}$ is the estimate computed from the reduced sample of 1,412 clusters (i^{th} cluster excluded),
and
 k is the total number of clusters.

In addition to the standard error, ISSA computes the design effect (DEFT) for each estimate, which is defined as the ratio between the standard error using the given sample design and the standard error that would result if a simple random sample had been used. A DEFT value of 1.0 indicates that the sample design is as efficient as a simple random sample, while a value greater than 1.0 indicates the increase in the sampling error due to the use of a more complex and less statistically efficient design. ISSA also computes the relative error and confidence limits for the estimates.

Sampling errors for the 1997 IDHS are calculated for selected variables considered to be of primary interest. The results are presented in this appendix for the country as a whole, for urban and rural areas, for three survey regions (Java-Bali, Outer Java-Bali I, and Outer Java-Bali II), and for each of the 29 provinces. For each variable, the type of statistic (mean, proportion, or rate) and the base population are given in Table B.1. Tables B.2 to B.35 present the value of the statistic (R), its standard error (SE), the number of unweighted (N) and weighted (WN) cases, the design effect (DEFT), the relative standard error (SE/R), and the 95 percent confidence limits ($R \pm 2SE$), for each variable. The DEFT is considered undefined when the standard error considering simple random sample is zero (when the estimate is close to 0 or 1). In the case of the total fertility rate, the number of unweighted cases is not relevant, as there is no known unweighted value for woman-years of exposure to child-bearing.

The confidence interval (e.g., as calculated for *children ever born to currently married women age 15-49*) can be interpreted as follows: the overall average from the national sample is 2.817 and its standard error is 0.025. Therefore, to obtain the 95 percent confidence limits, one adds and subtracts twice the standard error to the sample estimate, i.e., $2.817 \pm 2 \times 0.025$. There is a high probability (95 percent) that the *true* average number of children ever born to all currently married women age 15 to 49 is between 2.768 and 2.866.

Sampling errors are analyzed for the national sample and for two separate groups of estimates: (1) means and proportions, and (2) complex demographic rates. The relative standard errors (SE/R) for the means and proportions range between 0.2 percent and 19.4 percent with an average of 3.4 percent; the highest relative standard errors are for estimates of very low values (e.g., *currently using condoms*). It

should be noted that at the provincial level, sampling errors of some variables should be used with caution. For estimates based on a small number of cases, the relative error is quite large. For example, in the province of Lampung, the proportion of children with diarrhea in the last 2 weeks who were medically treated is 63.3 percent and is based on 47 cases. The relative error for this estimate is 46 percent.

If estimates of very low values (less than 10 percent) were removed, then the average would drop to 2 percent. So in general, the relative standard errors for most estimates for the country as a whole is small, except for estimates of very small proportions. The relative standard error for the total fertility rate is small, 1.9 percent. However, for the mortality rates, the average relative standard error is much higher, 7.3 percent.

There are differentials in the relative standard error for the estimates of sub-populations. For example, for the variable *with secondary education or higher*, the relative standard errors as a percent of the estimated mean for the whole country, for the rural areas, and for East Timor are 2.3 percent, 3.6 percent, and 13.1 percent, respectively.

For the total sample, the value of the design effect (DEFT), averaged over all variables, is 2.05 which means that, due to multi-stage clustering of the sample, standard deviation increased by a factor of 2.05 over that in an equivalent simple random sample.

Table B.1 List of selected variables for sampling errors, Indonesia 1997

Variable	Estimate	Base Population
Urban residence	Proportion	Ever-married women 15-49
No education	Proportion	Ever-married women 15-49
With secondary education or higher	Proportion	Ever-married women 15-49
Currently married	Proportion	Ever-married women 15-49
Married before age 20	Proportion	Ever-married women 15-49
Had first sexual intercourse before 18	Proportion	Ever-married women 15-49
Children ever born	Mean	Currently married women 15-49
Children ever born to women over 40	Mean	Currently married women aged 40-49
Children surviving	Mean	Currently married women 15-49
Knowing any contraceptive method	Proportion	Currently married women 15-49
Knowing any modern contraceptive method	Proportion	Currently married women 15-49
Ever used any contraceptive method	Proportion	Currently married women 15-49
Currently using any method	Proportion	Currently married women 15-49
Currently using a modern method	Proportion	Currently married women 15-49
Currently using pill	Proportion	Currently married women 15-49
Currently using IUD	Proportion	Currently married women 15-49
Currently using injection	Proportion	Currently married women 15-49
Currently using implants	Proportion	Currently married women 15-49
Currently using condom	Proportion	Currently married women 15-49
Currently using female sterilization	Proportion	Currently married women 15-49
Currently using male sterilization	Proportion	Currently married women 15-49
Currently using periodic abstinence	Proportion	Currently married women 15-49
Currently using withdrawal	Proportion	Currently married women 15-49
Using public sector source	Proportion	Current users of modern method
Want no more children	Proportion	Currently married women 15-49
Want to delay at least 2 years	Proportion	Currently married women 15-49
Ideal number of children	Mean	Ever-married women 15-49
Mothers received tetanus injection	Proportion	Births in last 5 years
Mothers received medical care at birth	Proportion	Births in last 5 years
Had diarrhea in the last 2 weeks	Proportion	Children under 5
Treated with ORS packets	Proportion	Children under 5 with diarrhea in last 2 weeks
Sought medical treatment	Proportion	Children under 5 with diarrhea in last 2 weeks
Having health card	Proportion	Children 12-23 months
Received BCG vaccination	Proportion	Children 12-23 months
Received DPT vaccination (3 doses)	Proportion	Children 12-23 months
Received polio vaccination (3 doses)	Proportion	Children 12-23 months
Received measles vaccination	Proportion	Children 12-23 months
Fully immunized	Proportion	Children 12-23 months
Total fertility rate (3 years)	Rate	Women-years of exposure to child-bearing
Neonatal mortality rate (0-9 years) ¹	Rate	Number of births
Infant mortality rate (0-9 years) ¹	Rate	Number of births
Child mortality rate (0-9 years) ¹	Rate	Number of births
Under five mortality rate (0-9 years) ¹	Rate	Number of births
Postneonatal mortality rate (0-9 years) ¹	Rate	Number of births

¹ For the total country is based in the period (0-4 years)

APPENDIX C

QUALITY OF THE DATA: NON-SAMPLING ERRORS

APPENDIX C

QUALITY OF THE DATA: NON-SAMPLING ERRORS

This appendix provides an initial assessment of the quality of the 1997 IDHS data. For this purpose, misreporting of ages, respondent's recall problems and other problems encountered during data collection are investigated.

Table C.1 presents the distribution of the household population by single years of age. Contrary to expectation, the proportion of children reported to be five years of age at the time of the survey is smaller than the proportions age four and six. This phenomenon is more significant for males than for females. Heaping is observed in the reporting of ages ending with 0 and 5 in the older ages for both males and females. The overreporting of women at age 50, and to a lesser extent, of females. The overreporting of women at age 50 may reflect age displacement as well as heaping, since age 49 is the upper limit of eligibility for the individual interview.

Table C.1 Household age distribution

Single-year age distribution of the de jure household population by sex (weighted), Indonesia 1997

Age	Males		Females		Age	Males		Females

					Total	73,459	100.0	74,214	100.0

Table C.2 shows that during the household interview, 39,153 women age 15-49 were recorded, among whom 29,203 have been married and are, therefore, eligible for individual interview. Of these women, 28,699 were successfully interviewed, yielding a response rate of 98 percent. The five-year age distribution of women follows the expected pattern. Compared with findings from past surveys, there is a decrease in the proportion of women 15-29, and an increase of the proportion of women 30-34.

Table C.2. Age distribution of eligible and interviewed women

Percent distribution of the de jure household population of women age 10-54, of ever-married women age 15-49, and of interviewed women age 15-49, and the percentage of eligible women who were interviewed (weighted) by five-year age groups, Indonesia 1997

Age	Household population of women		Ever-married women		Interviewed women		Percentage of eligible women interviewed (weighted)
	Number	Percent	Number	Percent	Number	Percent	
10-14	8,495	NA	NA	NA	NA	NA	NA
15-19	7,445	19.0	1,344	4.6	1,308	4.6	97.4
20-24	6,495	16.6	4,153	14.2	4,068	14.2	98.0
25-29	6,381	16.3	5,479	18.8	5,415	18.9	98.8
30-34	5,724	14.6	5,419	18.6	5,341	18.6	98.6
35-39	5,421	13.9	5,288	18.1	5,163	18.0	97.6
40-44	4,150	10.6	4,031	13.8	3,976	13.9	98.6
45-49	3,505	9.0	3,449	11.8	3,386	11.8	98.2
50-54	3,013	NA	NA	NA	NA	NA	NA
15-49	39,121	100.0	29,162	100.0	28,657	100.0	98.3

Note: The de jure population includes all usual residents of the household. The number of interviewed women is calculated using the household weights in order to be comparable with the number of ever-married women in the household. Thus, the numbers differ slightly from those shown in the rest of the report, which are based on individual woman weights.
NA = Not applicable

To investigate the possibility of bias in age reporting in the individual woman's interview, the age distribution of ever-married women (i.e., eligible women) was calculated from the household information and then compared with the age distribution of interviewed women (Table C.2). The expected pattern of declining percentage with increasing age, seen in the household population of women, is not repeated for ever-married women. At the same time, there is virtually no difference in the age distributions of ever-married women and interviewed women. This suggests that there is no bias in age reporting in these populations. Response rates vary slightly by age group.

Information on the completeness of reporting in connection with a set of important variables is provided in Table C.3. Among births in the 15 years preceding the survey, the percentage of cases with missing information on months and year of birth or age at death is extremely low (less than 1 percent). Comparing these percentages in this table and those found in the 1991 and 1994 Indonesia DHS, the reporting of dates is seen to have improved slightly (CBS et al., 1992 and CBS et al., 1995).

Comparing the figures presented in Table C.4 with those in previous Indonesia DHS data also suggests that the reporting of children's date of birth is slightly more complete in 1997 than in previous years.

Table C.3 Completeness of reporting

Percentage of observations missing information for selected demographic and health questions (weighted), Indonesia 1997

Subject	Reference group	Percentage missing information	Number of cases
Birth date	Births in last 15 years		
Month only		8.38	49,840
Month and year		0.03	49,840
Age at death	Deaths to births in last 15 years	0.01	3,767
Age/date at first union ¹	Ever-married women	0.01	28,810
Respondent's education	All women	0.00	28,810
Child's size at birth	Births in last 59 months	0.35	10,042
Diarrhea in last 2 weeks	Living children age 0-59 months	1.00	15,433

¹Both year and age missing

From the same table, the percentage of surviving children in the last 15 years with known month and year of birth is 100 percent in 1995-97, compared with 92 percent or less in the preceding. For dead children, the percentages are 100 and 72 percent, respectively. Sex ratios vary year by year without any indication of bias. However, women seem to have better recall of dead male children than dead female children, as indicated by the much higher sex ratios for dead children. Observing the calendar ratios, there seems to be a deficit of birth in 1991, and a surplus in 1990 (Figure C.1). For all births, the ratio of births in 1991 to the average of the two adjoining years is 0.86, and for births in 1990 it is 1.17. The phenomenon is more serious among dead children where the deficit also occurs for births in 1992. These numbers may represent a deliberate attempt by some interviewers to reduce their work loads, in particular to shorten the interview by skipping the health sections which ask extensive questions about children under five.

Table C.5 shows that the proportion of early neonatal deaths among all neonatal deaths is consistent with declining infant mortality rates. The same conclusion can be drawn from higher proportion of neonatal deaths among all deaths (Table C.6). Table C.6 shows that there is a heaping in age at death in multiple of 6 months.

Table C.4 Births by calendar years

Distribution of births by calendar years for living (L), dead (D), and all (T) children, according to reporting completeness, sex ratio at birth, and ratio of births by calendar year, Indonesia 1997

TICK HERE IF CONTINUATION SHEET USED ☐

NUMBER OF FAMILY ☐

Just to make sure that I have a complete listing:

- Are there any other persons such as small children or infants that we have not listed?
- Are there any other people who may not be members of your family, like servants, friends, lodgers, but who usually live here?
- Are there any other guests or visitors who have been temporarily staying with you for the past 6 months or more?
- Are there any persons who usually live here who have been away for less than 6 months?
- Are there any persons we have listed who have been away for the past six months?

SECTION 1. RESPONDENT'S BACKGROUND

NO.	QUESTIONS AND FILTERS	CODING CATEGORIES	SKIP TO
101	RECORD THE TIME.	HOUR..... MINUTES.....	
102	First I would like to ask some questions about you. For most of the time until you were 12 years old, did you live in a city, in a town, or in a village?	CITY.....1 TOWN.....2 VILLAGE.....3	
105	In what month and year were you born? WRITE MONTH IF NOT IN WESTERN CALENDAR MONTH: _____	MONTH..... DON'T KNOW MONTH.....98 YEAR..... DON'T KNOW YEAR.....9998	
106	How old were you at your last birthday? COMPARE AND CORRECT 105 AND/OR 106 IF INCONSISTENT.	AGE IN COMPLETED YEARS.....	
106A	Are you now married, divorced or widowed?	MARRIED.....1 DIVORCED.....2 WIDOWED.....3	
107	Have you ever attended school?	YES.....1 NO.....2	→114
108	What is the highest level of school you attended: primary, junior high, senior high, academy, or university?	PRIMARY.....1 JUNIOR HIGH SCHOOL.....2 SENIOR HIGH SCHOOL.....3 ACADEMY.....4 UNIVERSITY.....5	
109	What is the highest (GRADE, FORM, YEAR) you completed at that level? COMPLETED = 7	GRADE.....	
110	CHECK 106: AGE LESS THAN 25 <input type="checkbox"/> AGE 25 OR ABOVE <input type="checkbox"/>		→113
111	Are you currently attending school?	YES.....1 NO.....2	→113
112	What was the main reason you stopped attending school?	GOT PREGNANT.....01 GOT MARRIED.....02 TO CARE FOR CHILDREN.....03 FAMILY NEEDED HELP ON FARM OR IN BUSINESS.....04 COULD NOT PAY SCHOOL FEES.....05 NEEDED TO EARN MONEY.....06 GRADUATED/HAD ENOUGH SCHOOLING.....07 DID NOT PASS EXAMS.....08 DID NOT LIKE SCHOOL.....09 SCHOOL NOT ACCESSIBLE/TOO FAR.....10 OTHER.....96 (SPECIFY) DK.....98	
113	CHECK 108: PRIMARY <input type="checkbox"/> JUNIOR HIGH OR HIGHER <input type="checkbox"/>		→115
114	Can you read and understand a letter or newspaper easily, with difficulty, or not at all?	EASILY.....1 WITH DIFFICULTY.....2 NOT AT ALL.....3	→116

NO.	QUESTIONS AND FILTERS	CODING CATEGORIES	SKIP TO
115	Do you usually read a newspaper or magazine at least once a week?	YES.....1 NO.....2	
116	Do you usually listen to a radio every day?	YES.....1 NO.....2	
117	Do you usually watch television at least once a week?	YES.....1 NO.....2	
118	What religion are you?	MUSLIM.....1 PROTESTANT/CHRISTIAN.....2 CATHOLIC.....3 HINDU.....4 BUDDHIST.....5 OTHER.....6 (SPECIFY)	
119	What is the language used at home?	INDONESIAN.....01 JAVANESE.....02 SUNDANESE.....03 BATAK.....04 MINANG.....05 BUGINESE.....06 OTHER.....96 (SPECIFY)	→201
120	Can you speak Bahasa Indonesia? IF INTERVIEW IS IN BAHASA INDONESIA, DON'T ASKED THIS QUESTIONS. CIRCLE CODE 1.	YES.....1 NO.....2	

SECTION 2. REPRODUCTION

NO.	QUESTIONS AND FILTERS	CODING CATEGORIES	SKIP TO
201	Now I would like to ask about all the births you have had during your life. Have you ever given birth?	YES.....1 NO.....2	→206
202	Do you have any sons or daughters to whom you have given birth who are now living with you?	YES.....1 NO.....2	→204
203	How many sons live with you? And how many daughters live with you? IF NONE, ENTER '00'.	SONS AT HOME..... DAUGHTERS AT HOME.....	
204	Do you have any sons or daughters to whom you have given birth who are alive but do not live with you?	YES.....1 NO.....2	→206
205	How many sons are alive but do not live with you? And how many daughters are alive but do not live with you? IF NONE ENTER '00'.	SONS ELSEWHERE..... DAUGHTERS ELSEWHERE.....	
206	Have you ever given birth to a boy or a girl who was born alive but later died? IF NO, PROBE: Any baby who cried or showed any sign of life but survived only a few hours or days?	YES.....1 NO.....2	→208
207	In all, how many boys have died? And how many girls have died? IF NONE, ENTER '00'.	BOYS DEAD..... GIRLS DEAD.....	
208	SUM ANSWERS TO 203, 205, AND 207, AND ENTER TOTAL. IF NONE, ENTER '00'.	TOTAL.....	
209	CHECK 208: Just to make sure that I have this right: you have had in TOTAL _____ live births during your life. Is that correct? YES <input type="checkbox"/> NO <input type="checkbox"/> PROBE AND CORRECT 201-208 AS NECESSARY		
210	CHECK 208: ONE OR MORE LIVE BIRTH <input type="checkbox"/> NO LIVE BIRTHS <input type="checkbox"/>		→223

211 Now I would like to record the names of all your births, whether still alive or not, starting with the first one you had.

RECORD NAMES OF ALL THE BIRTHS IN 212. RECORD TWINS AND TRIPLETS ON SEPARATE LINES

212	213	214	215	216	217 IF ALIVE:	218 IF ALIVE:	219 IF DEAD:	220 INTERVAL CHECK:
What name was given to your (first, next) baby?	Were any of these births twins?	Is (NAME) a boy or a girl?	In what month and year was (NAME) born? PROBE: What is his/her birthday?	Is (NAME) still alive?	How old was (NAME) at his/her last birthday? RECORD AGE IN COMPLETED YEARS	Is (NAME) living with you?	How old was he/she when he/she died? If "1 YEAR", PROBE: How many months old was (NAME)? RECORD DAYS IF LESS THAN 1 MONTH; MONTHS IF LESS THAN TWO YEARS, OR YEARS IF TWO YEARS OR ABOVE. IF LESS THAN ONE DAY, WRITE '00' IN DAYS BOX.	CALCULATE THE DIFFERENCE BETWEEN THE YEAR OF BIRTH OF (NAME) AND THE YEAR OF THE PRECEDING BIRTH: IF 4 YEARS OR MORE, ASK: Were there any other live birth between the birth of (NAME) and (NAME OF PRECEDING BIRTH)?
