**KENYA
CONTRACEPTIVE PREVALENCE
SURVEY
1984**

PROVINCIAL REPORT

MAY 1986

**CENTRAL BUREAU OF STATISTICS
MINISTRY OF PLANNING AND NATIONAL DEVELOPMENT
NAIROBI, KENYA**

This report presents provincial findings from the Kenya Contraceptive Prevalence Survey which was implemented by the Central Bureau of Statistics. The survey is part of the worldwide Contraceptive Prevalence Survey (CPS) project designed to institutionalize the monitoring of levels of contraceptive awareness, availability, and use in order to provide an improved data base for evaluating family planning programmes.

Additional information on this survey can be obtained from the Central Bureau of Statistics, P. O. Box 30266, Herufi House, Lt. Tumbo Street, Nairobi, Kenya.

Information on the Contraceptive Prevalence Survey programme can be obtained from the Institute for Resource Development at Westinghouse, P. O. Box 866, Columbia, Maryland 21044, U.S.A. (Telex Number 87775).

FOREWORD

The first five-year National Sample Survey Programme in Kenya was initiated by the Central Bureau of Statistics in 1974, and the second phase of the Survey Programme was started in 1980. An identifiable area sample was always used as the point of reference for the collection of data from all the sample households or a sub-sample of households depending on the requirements of each respective survey.

Surveys conducted within the programme have collected data on social and economic characteristics of the household. Social surveys have tended to be biased more on the study of demographic levels and trends. Demographic surveys which have been conducted within the sample survey programme include National Demographic Surveys I (1977), II (1978), and III (1983); Kenya Fertility Survey, 1977/78; and Contraceptive Prevalence Survey, 1984. Other social surveys include Literacy Survey, 1976/77 and 1980/81, and Nutrition Survey, 1977, 1978/79, and 1982. Most of the data generated by these surveys are available in the Central Bureau of Statistics data bank and, therefore, form a large data base for further research aimed at more understanding of the Kenyan population.

The Kenya Contraceptive Prevalence Survey, after the Kenya Fertility Survey, is the second most complex demographic type of survey to have been undertaken by the Central Bureau of Statistics. The results of the survey have been published as the main survey report. This report focuses on the results at the provincial level which can be useful in planning population programmes at the local level.

I would like to acknowledge assistance by the United States Agency for International Development for financial support, Westinghouse Health Systems which gave invaluable consultancy service; and also the National Council for Population Development, the Division of Family Health (MCH/FP) and the Population Studies and Research Institute which gave the project advice and support.

INTRODUCTION

The major purpose of this report is to present, in a tabular form, data from the 1984 Kenya Contraceptive Prevalence Survey which can be used by researchers to assess family planning programme needs and develop recommendations for providing contraceptive services at the local level. The report focuses on the the major findings of the KCPS at the provincial level; the results at the national level are presented in a separate report. Provinces for which data are presented include Nairobi, Coast, Eastern, Central, Rift Valley, Nyanza, and Western. It should be noted that the entire North-Eastern Province as well as the districts of Samburu and Turkana in Rift Valley Province and of Isiolo and Marsabit in Eastern Province were not covered in the KCPS sample.

In considering the tables presented in this report, it should be borne in mind that the KCPS sample was drawn in such a manner as to have reliable results only at the national and provincial level.¹ Thus, although results are shown for some variables for districts, these tabulations should be interpreted with caution because of the small sample size for many districts.

Organization of the Report

Each of the tables is organized by province. The topics covered for each province include:

- Background Characteristics (Tables 1.1-1.4)
- Nuptiality, Fertility, and Reproductive Intentions (Tables 2.1-2.10)
- Knowledge and Use of Contraceptive Methods (Tables 3.1-3.4)
- Availability of Contraceptives (Tables 4.1-4.3)
- Women at Risk (Tables 5.1-5.3)

A brief commentary on the results for each province precedes the provincial tabulations.

¹ For a more complete description of the KCPS sample design and methodology the readers are referred to Central Bureau of Statistics, Kenya Contraceptive Prevalence Survey 1984, Nairobi: Central Bureau of Statistics.

NAIROBI PROVINCE

General Characteristics (*Tables 1.1-1.4*)

A total of 625 urban women were interviewed in Nairobi Province; there are no rural areas in the province.

The age distribution for the KCPS respondents from Nairobi is similar to the projected age distribution of women aged 15-49 in the province based on the 1979 census. In general, the Nairobi sample has a young age structure. The mean age is only 25 years.

The educational level and literacy rate of Nairobi women is high. More than 75 per cent have five or more years of formal schooling. A substantial majority of the respondents can read Swahili, English, or a tribal language; only 12 per cent are illiterate. Younger women are generally more educated than older women. For example, women in the 15-24 age group are nearly twice as likely to have more than a primary education than women aged 35-49.

Female labor force participation rates in Nairobi are the highest for any province. Four out of every ten women have ever worked for pay, and one-third of the women were in the labor force at the time of the KCPS.

Almost all of the currently married women have literate husbands and more than half of the husbands have at least a primary education. Three-fourths of the husbands are employed in business or industry, 13 per cent are self-employed and nine per cent work in agriculture.

Nuptiality, Fertility and Reproductive Intentions

Nuptiality (*Tables 2.1-2.3*)

Among the women interviewed in Nairobi Province, one-third are reported as never married, 61 per cent are currently married and the rest are widowed, divorced or separated. The data on age at marriage suggest that the majority of women marry before their 20th birthday. Only one out of every three ever-married women first married after age 19.

Among currently married women, 16 per cent are in polygamous unions. Polygamous unions are not, however, as common in the age group 15-34 as they are in the oldest cohorts. More than one-third of the women aged 35-49 have one or more co-wives compared to less than one-sixth of women aged 15-34.

Fertility (Tables 2.4-2.6)

The mean number of ever born and surviving children for Nairobi are 2.4 and 2.1, respectively. Parity increases rapidly with age, and completed fertility (the mean number of children ever born to women age 45-49) exceeds five births. A comparison with the national figures indicates that, although fertility levels are high in Nairobi, they are much lower than the level that prevails in Kenya as a whole where completed parity is over eight births.

An examination of several other indicators suggests current fertility levels remain high in Nairobi, although again substantially below that reported for Kenya as a whole. The total fertility rate is 5.6, and ten per cent of the respondents were pregnant at the time of the interview.

Reproductive Intentions (Tables 2.7-2.10)

Regarding the reproductive intentions of currently married fecund women, almost one-third do not desire any more children (12 per cent wanted to stop having children before they became pregnant the last time), 42 per cent want to space and 20 per cent want to get pregnant soon. The desire to limit the family to its present size increases with age and the number of living children, peaking at 83 per cent among women in the 35-49 age group.

An examination of the intentions of both the woman and her spouse indicates that, in the case of 55 per cent of the couples, both the woman and her spouse want to have more children in the future while only around 20 per cent of the couples agree that they do not want more children.

The ideal family size is 4.3 children, more than one child fewer than the number the average woman will have if fertility continues at current levels. The ideal family size is slightly higher for those currently married than for those who are not in union. Work status is not important in determining the ideal family size, but illiterate women seem to desire more children than literate women.

Knowledge and Use of Contraceptives (Tables 3.1-3.4)

Eighty-five per cent of Nairobi women know at least one contraceptive method. Medical service agencies are the major source of family planning information among those who mention knowing any method.

Thirty-six per cent of Nairobi women have ever used contraception and most ever users have used modern methods. The proportion of women currently using contraceptives is 23 per cent.

Both awareness and use of family planning methods are slightly higher among women aged 25-34, literate women with literate spouses, women with post-primary education, women with two or more living children and among

women who want no more children now or who did not want more before the last pregnancy than among women in other population sub-groups.

The major reasons for not currently using a method are: not sexually active/infertile (23 per cent), lack of knowledge (9 per cent) and disapproval of family planning (8 per cent).

Almost eight out of every ten women knowing about family planning but currently not contracepting approve of family planning. Husbands are not as likely to approve of family planning as their wives. Only 58 per cent of husbands are reported by their wives to approve of family planning. However, the husband's disapproval does not appear to have a major influence on a woman's intention to use family planning; nearly eight out of every ten non-users who know about family planning intend to use it in the future.

The pill is the most widely known and ever used method, and it is the preferred method among current non-users. Among current users, however, the IUD is the most frequently used method followed by the pill, periodic abstinence (rhythm), female sterilization and the condom.

Availability (Tables 4.1-4.3)

In Nairobi Province, 60 per cent of the women not using a modern method but knowing some method are aware of a family planning outlet; most mention hospitals or clinics as their preferred source. More than one-half of the women would walk to the source they prefer. The median time to a service outlet is less than 30 minutes, but 16 per cent of the women expect to spend an hour or more to travel to their preferred source.

Forty-two per cent have been to the source they prefer to obtain family planning information or services. Only five per cent of them have some reservations about the use of the source.

Field educator activities are limited in Nairobi Province; only nine per cent have ever been visited by a field educator. Almost one-fourth of the women mentioned Saturday and afternoons as their preferences for the day and time for field educator visits.

At Risk (Tables 5.1-5.3)

One-fifth of the women in Nairobi Province are at risk of an unplanned (13 per cent) or unwanted (7 per cent) pregnancy. The total at risk is practically the same in all age groups, but the risk of an unwanted pregnancy increases sharply with age. Illiterate women and those without schooling are slightly more likely to be at risk than other women.

Among women at risk of unwanted pregnancy, one in five does not know about family planning, four out of every five have never used a method and around one out of every two does not know a source for contraceptives. Slightly more than one out of every four either does not know

NAIROBI PROVINCE

a method or does not intend to use a method in the future. Those who are at risk of an unplanned pregnancy (i.e., younger women) are slightly more knowledgeable about methods and an outlet and are more likely to intend to use family planning in the future than those at risk of an unwanted pregnancy (i.e., older women).

COAST PROVINCE

General Characteristics (Tables 1.1-1.4)

A total of 1,313 women were interviewed in Coast Province. Seven out of ten of these women live in rural areas.

The age distribution of the KCPS sample for Coast Province is very similar to census projection for the province. Forty-four per cent of the women are below 25 years while 26 per cent are 35 years or more. The mean age of the respondents (27.7 years) is identical to that reported for the KCPS sample as a whole.

Female education levels, literacy and labor force participation rates are low in the province. More than half of the women have no schooling, and 52 per cent are illiterate. Considering education by age, slightly more than 62 per cent of the women in age group 15-24 have ever attended school compared to 38 per cent and 21 per cent in the age groups 25-34 and 35-49, respectively.

Three-fourths of the respondents have never worked, and only one-sixth were working at the time of the interview.

Husbands are more likely than their wives to have attended school; only slightly more than one out of every four men is illiterate. With regard to male labor force participation, 26 per cent of the husbands work in farming, 50 per cent are working in other occupations and 22 per cent are not currently working.

Nuptiality, Fertility and Reproductive Intentions

Nuptiality (Tables 2.1-2.3)

Seven out of every ten respondents from Coast Province are currently married, one out of every ten was married in the past and the remaining respondents are reported as never married. More than one-half of the ever-married women first married before their 18th birthday, and only 25 per cent were still unmarried by the time they were 20 years old.

Polygamy is very prevalent in Coast Province. Overall, 31 per cent of currently married women have one or more co-wives and even among women younger than 25 years, one-fourth are in polygamous unions.

Fertility (Tables 2.4-2.6)

The mean number of ever born and surviving children for Coast Province are 3.4 and 2.7, respectively. One-fourth of the women have had more than five children and, among older women (35-49), almost six out of every ten have had that many children. On average, the 40-49 year old women have had more than six births.

Current fertility levels are high, with the total fertility rate approaching seven births. About 10 per cent of the respondents were pregnant at the time of the interview.

Reproductive Intentions (Tables 2.7-2.10)

One out of every five currently married fecund women in Coast Province does not want to have more children in the future (10 per cent did not desire another child before their last pregnancy). One out of every three women wants to space, a similar proportion is seeking a pregnancy now, while the remainder do not know whether they want more children or not. The desire to limit family size increases with age; however, it is significant that even among the oldest cohorts, only four out of every ten women do not want more children.

As for the couple's future reproductive intentions, 60 per cent of all couples agree that they want more children while ten per cent do not want anymore. In 18 per cent of the couples, the wife or the husband wants to stop having children but their spouse does not.

The ideal family size for women living in Coast Province is high (6.1 children). Age clearly affects family size desires; the mean ideal size is much lower among younger never married women (4.5) than among currently married women (6.7). Educational levels and literacy status also are related to family size desires. Illiterate couples want to have larger families (7.5 children) than literate couples (5.6 children).

Knowledge and Use of Contraceptives (Tables 3.1-3.4)

Eighty per cent of women have knowledge of at least one contraceptive method. Women in the age groups 15-24 and 35-49, unmarried women, those with no schooling, those with none or one child, illiterate couples and women whose husbands own farms have somewhat lower levels of knowledge than women in other population sub-groups. Medical service agencies and media are the major sources of knowledge for those who could mention at least one method without prompting.

Only about one out of every six women in Coast Province (18 per cent) has ever used a contraceptive method, and, among those who have ever used, around one out of every two has used only a traditional method. The per cent of all women 15-49 who are currently using family planning (9 per cent) is substantially lower than the national average (15 per cent).

The level of ever use and current use of family planning is higher than for the population as a whole among those who have ever been in union, those with two or more children and those with husbands working in non-farming occupations. Literacy status and educational levels also are positively related to use. Twenty per cent of literate couples are currently using a contraceptive method compared to only two per cent of illiterate couples. Women with more than primary education have the highest prevalence rate (24 per cent).

The three most widely recognized methods in Coast Province are the pill, injection and female sterilization. More women have ever used the pill than any other method, followed by periodic abstinence (rhythm) and prolonged abstinence. Methods currently used by one per cent or more of the respondents are: pill (3 per cent), periodic abstinence (rhythm) (2 per cent), and female sterilization and prolonged abstinence (each one per cent). The most frequently preferred methods among non-users intending to use in the future are the pill (45 per cent) and injection (27 per cent).

The major reasons for non-use mentioned by those currently not using a method are: not sexually active/infertile (17 per cent), want to get pregnant (15 per cent), not convinced/not thought (11 per cent) and lack of knowledge (8 per cent).

Seventy-five per cent of all women knowing a method approve of family planning and 81 per cent intend to use in the future. This suggests that some who do not approve still plan to use a contraceptive method in the future. Women who are unmarried, those in the age group 25-34, those who have some education, those currently working, those wanting to space, those whose husbands work on someone else's farm and those who are literate and whose husbands are literate are more likely to approve than those in other sub-groups. With a few exceptions, they also are likelier to intend to use in the future than other women.

Women report that their husbands are less likely to approve of family planning than they are themselves. Only 54 per cent of women think that their husbands approve of family planning.

Availability (Tables 4.1-4.3)

Around four out of ten respondents who know some contraceptive method and are not using a modern method said that they know a family planning outlet. Knowledge of an outlet is most common among women in the 25-34 age group, those currently working, those who are literate and those who, along with their husbands, do not want more children.

Hospitals and clinics were mentioned as preferred sources by 64 per cent and 32 per cent, respectively, of those knowing an outlet. More than one-half of these non-users knowing a source would have to travel one hour or more to their preferred source, while only one-fourth can reach the outlet in less than thirty minutes. Fifty per cent would walk to the source. Around six out of every ten non-users knowing an outlet have used the source.

The field educator has ever visited only 12 per cent of the women. Of the women visited by a field educator, only one-third have been visited within the last three months. One-third of the women have no preference regarding the time for a field educator's visit, while one-fourth prefer a visit in the morning. As for the preferred day for a field educator's visit, 28 per cent would like the field educator to visit them on the weekend.

At Risk (Tables 5.1-5.3)

More than one-fifth of the women in Coast Province are at risk of an unplanned (11 per cent) or unwanted pregnancy (11 per cent). The total per cent at risk by age is 19 per cent for the 15-24 age group, 26 per cent for the age group 25-34 and 24 per cent for the age group 35-49. With regard to other characteristics, women with less than five years of schooling, and literate women whose spouses are literate are slightly more likely to be at risk than other categories.

EASTERN PROVINCE

General Characteristics (Tables 1.1-1.4)

A total of 891 women were interviewed in Eastern Province. Almost all the respondents (98 per cent) lived in rural areas.

The age distributions of the KCPS sample and of the census projections for the province differ slightly for the age groups 15-19, 25-29 and 30-34. The KCPS distribution shows that 41 per cent of the women are below 25 years of age while 25 per cent are 35 years or older. The mean age of the respondents is 28 years.

One-third of the women have no schooling and 35 per cent are illiterate. Their educational level decreases significantly with increasing age. For example, while in the age group 35-49, 65 per cent have no education and only one per cent have 9 years or more of schooling, in the age group 15-24, only 12 per cent have not been to school and 31 per cent have at least some post-primary education.

Female participation in paid employment is not widespread. While 17 per cent of the women are currently working for pay and 10 per cent have worked in the past, over 70 per cent have never worked at a job for which they were paid.

The husbands of currently married women are more likely to be educated and literate than the women themselves. One-third of the husbands own a farm and another 10 per cent work on other people's farms. Forty-three per cent are employed in business. The remaining husbands (16 per cent) are not currently working.

Nuptiality, Fertility and Reproductive Intentions

Nuptiality (Tables 2.1-2.3)

Two-thirds of the women in Eastern Province are currently married, one-fourth have never married, and the remainder have been married in the past but currently are separated, divorced or widowed. Almost all women over the age of 24 have married. More than 60 per cent of ever-married women first married before their 20th birthday.

Polygamy is not as prevalent in Eastern Province as it is in the other provinces; only 15 per cent of currently married women are in a polygamous union. Even among women aged 35-49, only 20 per cent have one or more co-wives.

Fertility (Tables 2.4-2.6)

The mean number of ever born and surviving children for Eastern Province are 3.9 and 3.3, respectively. One-third of the women have had six or more children and, among older women (35-49), more than eight out of ten have had that many children. As in Kenya as a whole, completed fertility exceeds eight births.

Current fertility levels are high and, if there is no decline, the total fertility rate indicates that the average woman beginning her reproductive period at this time will have eight births before she reaches her 50th birthday. Approximately 11 per cent of the women were pregnant at the time of the interview.

Reproductive Intentions (Tables 2.7-2.10)

Forty-two per cent of the women want no more children in the future. One out of every four currently married fecund women in Eastern Province did not, in fact, want another child before the last pregnancy. Around one out of every four women wants to space her next birth, 18 per cent want another child soon while 13 per cent are not sure about their future reproductive intentions. The desire to stop having children increases with age, with two-thirds of currently married fecund women aged 35-49 saying that they do not want another child. As for the currently married women and their husbands' future reproductive intentions, 34 per cent of the couples want more children, 28 per cent do not want any more, ten per cent do not agree about their fertility intentions and 27 per cent are uncertain about their family size desires.

In spite of the high fertility of the women living in Eastern Province, the mean ideal family size is only 5.4 for all women. Never married women want to have, on average, only 4.2 children. Illiterate couples desire larger families (6.8) than literate couples (5.5). The ideal family size for women whose husbands own a farm or business is higher than for those whose husbands are employed on a farm or in a business.

Knowledge and Use of Contraceptives (Tables 3.1-3.4)

Eighty-eight per cent of women in Eastern Province know at least one contraceptive method. Unmarried and younger women (15-24) are less knowledgeable than married and older women. Knowledge of some contraceptive method is almost universal among currently working women and women who have four living children. The source of contraceptive knowledge for those who could name a method without prompting was: medical services (69 per cent), media (19 per cent) and church/barazas (14 per cent).

Ever use of contraception in the province is widespread (41 per cent) but less than one-half of all ever users have used modern methods. The

current use of contraceptives in Eastern Province is much higher (22 per cent) than the national average (15 per cent). Approximately 30 per cent of women age 25-49, those with 1-4 years of schooling and those with four children are currently using a method; usage levels in other population sub-groups tend to be lower than the average for the province.

The desire to have a child (12 per cent) and lack of contraceptive knowledge (12 per cent) are among the main reasons for non-use among non-pregnant, currently married non-users knowing some contraceptive method. About 16 per cent of the non-users also report they are not sexually active or they are infecund.

Among women who know some contraception and currently do not use a method, 74 per cent approve of family planning. Approval of family planning is slightly higher than the provincial average among women age 25-34, those with more than eight years of schooling, those currently working and those who have three or four children. Only about one out of every two husbands is seen by his wife as approving of family planning.

The five most widely recognized methods in Eastern Province are: pill (78 per cent), IUD (64 per cent), injection (60 per cent), female sterilization (60 per cent) and periodic abstinence (rhythm) (59 per cent). One-fifth of the women have ever used periodic abstinence (rhythm), and more than one out of every ten have used the pill or prolonged abstinence. Among those currently using a method, 30 per cent depend on periodic abstinence (rhythm), 22 per cent on the pill, 18 per cent on the IUD and 18 per cent on prolonged abstinence. Preferred methods mentioned by more than 10 per cent of the current non-users are: the pill (42 per cent), injection (24 per cent) and female sterilization (11 per cent).

Availability (Tables 4.1-4.3)

Only one out of every two respondents knowing some contraceptive method and not using a modern method knows a family planning outlet. The knowledge of a contraceptive supply source is lowest among illiterate women (32 per cent), women age 35-49 (37 per cent) and among illiterate women with illiterate husbands (22 per cent).

Hospitals and clinics are mentioned as preferred sources by 78 per cent and 22 per cent, respectively, of women knowing an outlet. Thirty-six per cent have been to the outlet for family planning information or services. Only 11 per cent are within 30 minutes travel time of the outlet they mention; 62 per cent expect to spend an hour or more to get to the outlet. More than 50 per cent of women say that they have to use transport to reach their preferred outlet. Less than 10 per cent feel that there is reason for not using the service outlet that they mention.

Only 13 per cent of the women have ever been visited by a field educator. Of those visited by an educator, 40 per cent have been visited within the last three months. With regard to preferences for the time for the field educator's visit, 28 per cent have no preference regarding

the time of day, and more than one-third have no preference about the day of visit. Among those expressing a preference, evenings are less popular than mornings and afternoons, and Saturday and Sunday are more popular than other days of the week.

At Risk (Tables 5.1-5.3)

More than one-fifth of the women in Eastern Province are at risk of an unwanted (11 per cent) or unplanned (10 per cent) pregnancy. The total at risk varies by age from 15 per cent among women aged 25-34 to 22 per cent and 28 per cent among those aged 15-24 and 35-49, respectively. Among women aged 15-24, most women are at risk of an unplanned pregnancy while, for the 35-49 age group, almost all women at risk are at risk of unwanted pregnancy.

Among those at risk of an unwanted or unplanned pregnancy, 12 per cent do not know any family planning method, 81 per cent have never used a method, 54 per cent do not know an outlet for a method and 25 per cent do not intend to use a method in the future.

CENTRAL PROVINCE

General Characteristics (Tables 1.1-1.4)

A total of 917 women were interviewed in Central Province. Among these women, only eight per cent were urban residents.

The age distributions of the KCPS sample and of the census projections for the province are very similar. The mean age of the KCPS respondents is 28 years; 46 per cent of the women are below 25 years old while 28 per cent are 35 years or older.

One out of every five women in the province has never attended school, and 22 per cent are reported as illiterate. Considering education by age, the results indicate that almost all women aged 15-24 have attended school while only 79 per cent and 51 per cent in the age groups 25-34 and 35-49, respectively, have some schooling.

Few women are in the active labor force. Only 14 per cent of the women are working for pay; a similar proportion has worked in the past.

Ninety per cent of currently married women have husbands who have some schooling and are literate. One-fourth of the husbands work in farming, 45 per cent own or are employed by a business and 30 per cent are not working.

Nuptiality, Fertility and Reproductive Intentions

Nuptiality (Tables 2.1-2.3)

Of the women interviewed in Central Province, 36 per cent are reported as never married, 56 per cent are currently married and seven per cent are widowed, divorced or separated. More than 70 per cent are never married in the age group 15-24 while only nine per cent and three per cent are not married in the age groups 25-34 and 35-49, respectively.

Polygamy is not as prevalent in Central Province as it is in other provinces. Only eight per cent of the currently married women are in polygamous unions. Polygamous unions are more common among women aged 35-49 than among younger women.

Fertility (Tables 2.4-2.6)

The mean number of ever born and surviving children for Central Province are 3.5 and 3.1, respectively. One-fourth of the women aged 25-34 have had six or more live births, and, among women in the age group 35-49, almost 80 per cent had more than five live births. Completed fertility averages around eight births. The total fertility rate is 7.8. In spite of the fact that the TFR is high, only eight per cent of the women were reported to be pregnant at the time of the interview.

Reproductive Intentions (Tables 2.7-2.10)

Four out of ten currently married fecund women in Central Province do not want to have any more children. Twenty-seven per cent did not, in fact, want another child at the time of their last pregnancy. One-third want to space their next birth while 13 per cent want a child 'soon.' The desire to stop child-bearing increases with age, with more than 60 per cent of women aged 35-49 wanting no more children in the future.

The mean ideal family size is 5.4 children for women living in Central Province. It is higher for currently married women (6.1) than for those not in union (4.3). Among currently married women, the ideal family size is higher when both husband and wife are illiterate (6.7) than when both are literate (5.7)

Knowledge and Use of Contraceptives (Tables 3.1-3.4)

Knowledge of contraceptive methods in Central Province is widespread; 90 per cent of the women know at least one method. More than 95 per cent of the women know some method among ever married women, women age 25-49 and women who have three or more children. Contraceptive knowledge is, moreover, almost universal among couples where both the husband and wife are literate. With regard to the source of family planning information, two-thirds of the women who could name at one method without prompting say that they first obtained information about contraceptives from the medical services (clinics, hospital, doctor), 13 per cent first got information from the media, while nine per cent named church/barazas as their information source.

Forty-three per cent of women in Central Province have ever used a method, but only around one out of every two of these women has used a modern method. Contraceptive prevalence in Central Province is the highest in Kenya; 27 per cent are currently using a method. Among the currently married, those 25 years or older, those who are working and those with four or more children, current use exceeds the provincial average, ranging between 34 per cent and 43 per cent.

One-fourth of all non-pregnant, currently married non-users are not currently using a method because they are not sexually active or are infertile. Other reasons given for non-use are: too young to use (10 per

cent), want to get pregnant (8 per cent), disapprove (7 per cent) and lack of knowledge (7 per cent).

Among non-users knowing about family planning, the proportions approving of family planning and intending to use in the future are identical (85 per cent). Husbands are not as likely as their wives to approve of family planning. Only 66 per cent of the husbands are seen as approving of family planning.

Considering knowledge, ever use and current use by specific method, the methods vary in both recognition and popularity. The pill (81 per cent), female sterilization (72 per cent), IUD (70 per cent) and injection (66 per cent) are more widely known than other methods. Considering the levels of ever use, periodic abstinence (rhythm) is the most frequently adopted method (20 per cent) followed by prolonged abstinence (16 per cent), the pill (11 per cent) and the IUD (7 per cent). Among current users, the method mix is as follows: periodic abstinence (rhythm) (27 per cent), female sterilization (19 per cent), IUD (16 per cent), prolonged abstinence (16 per cent) and the pill (12 per cent).

Method preferences among those who intend to use in the future suggest that the pill (38 per cent), injection (23 per cent), IUD (9 per cent), periodic abstinence (rhythm) (9 per cent) and female sterilization (8 per cent) are the most popular choices.

Availability (Tables 4.1-4.3)

In Central Province, 55 per cent of the women not using a modern method but knowing some method are aware of a family planning outlet. As in other provinces, hospitals and clinics are the most frequently preferred sources for contraceptives. Almost 40 per cent of the women have been to their preferred source for family planning information or services. The mean time to a family planning outlet is 74 minutes, and two-thirds of the women say that it would take than at least one hour to go to the outlet. Most of the women (60 per cent) would have to use transport to get to their preferred outlet.

Twenty-two per cent of the women knowing contraceptives and not using a modern contraceptive method have been visited by a field educator. Of these, only one-fourth were visited by a field educator in the last three months. More than 30 per cent of the women have no preference regarding the day for a field educator's visit, while 20 per cent do not have a preferred time for a visit. Of those expressing some preference, 40 per cent prefer afternoons and weekends.

At Risk (Tables 5.1-5.3)

In Central Province, 18 per cent of the women are at risk of an unplanned (10 per cent) or unwanted pregnancy (7 per cent). It should be noted that the total at risk slightly decreases with an increase in the

CENTRAL PROVINCE

age of the woman. For the women in the age group 25-34, the proportions of women at risk of unwanted and unplanned pregnancy are almost the same. More women are at risk of unplanned pregnancy among the younger women (15-24) while, in contrast, among the women aged 35-49 more are at the risk of unwanted pregnancy.

Among women at risk, four per cent do not know about contraceptives, 81 per cent have never used a family planning method, 45 per cent do not know any family planning outlet and 21 per cent do not intend to use a method in the future. There are only slight variations in these indicators between those at risk of unplanned pregnancy and those at risk of unwanted pregnancy.

RIFT VALLEY PROVINCE

General Characteristics (Tables 1.1-1.4)

A total of 864 women were interviewed in Rift Valley Province. The sample is 90 per cent rural and 10 per cent urban.

The age distributions of the KCPS sample and of the census projection for the province are very similar. The mean age of the respondents is 28 years; 43 per cent of the respondents are below 25 years, while 29 per cent are 35 years or over.

The educational level and literacy rates for women are low in the province. About four out of every ten women are illiterate. The level of education varies significantly by age. Thirty per cent of the women in the age group 25-34 have more than 4 years of schooling, while 66 per cent of the younger and 12 per cent of the older women have the same level of education.

Most women have never held jobs for which they were paid. Around one-third of the women have ever worked for pay, and only one out of every five women were working at the time of the survey.

The educational level and literacy rate of the husbands of currently married women are much higher than those observed for the women themselves. More than three-fourths of the husbands are literate. Approximately one-third of the husbands work in farming and slightly more than one-quarter own or are employed in a business. A substantial proportion (36 per cent) were not, however, working at the time of the survey.

Nuptiality, Fertility and Reproductive Intentions

Nuptiality (Tables 2.1-2.3)

Two-thirds of the women interviewed in Rift Valley Province are currently married, one-fourth are reported as never married, and the remainder are separated, divorced or widowed. Of those who have married, 15 per cent first married before their 15th birthday, and only 24 per cent were married for the first time at age 20 or after.

Polygamy is common in Rift Valley Province. Overall, more than one out of every four currently married women has one or more co-wives. By age, the proportion with co-wives varies from 19 per cent of women aged 15-24 to 31 per cent among women aged 35-49.

Fertility (Tables 2.4-2.6)

The mean numbers of ever born and surviving children for Rift Valley Province are 4.1 and 3.5, respectively. Overall, one-third of the women have had six or more births and, among women aged 35-49, the proportion of women with more than five births increases to 75 per cent. Women in age group 45-49 have had, on the average, eight children.

Current fertility levels are similar to the levels prevailing in the past. The total fertility rate is 8.6. Nine per cent of the respondents were reported to be pregnant at the time of the interview.

Reproductive Intentions (Tables 2.7-2.10)

More than one-fourth of the currently married fecund women in Rift Valley do not want to have children in the future (14 per cent did not desire more children before their last pregnancy), one out of every two women wants to space her next child and only one out of every five women is seeking a pregnancy immediately. As for the couple's joint future reproductive intentions, in 52 per cent of the cases, both the husband and the wife want more children, while, in 14 per cent of the cases, neither the husband nor the wife want more. In 13 per cent of the cases, the husband and the wife do not agree on their family size desires, and, in one out of every five couples, either one or both spouses are not sure of their reproductive intentions.

The ideal family size for women living in Rift Valley Province (6.5 children) is the highest in Kenya. Women who are married to men who own a farm or whose husbands are not working desire larger than average families (7.3 and 7.8 children, respectively). The ideal family size reported by illiterate women with illiterate spouses is 8.4, while the ideal is 6.6 children among couples where both husband and wife are literate.

Knowledge and Use of Contraceptives (Tables 3.1-3.4)

Seventy per cent of women in Rift Valley know at least one contraceptive method. The level of knowledge does not differ substantially by marital status, age or the number of living children, but women who have attended school, who currently work or who have worked in the past, and literate women married to literate men are more likely to be aware of family planning methods than those who have no education or have never worked. Those who could name a contraceptive method without prompting attribute their knowledge of the contraceptive methods primarily to the medical services (60 per cent), followed by the media (17 per cent) and field educators (5 per cent).

More than one-fourth (28 per cent) of all women have ever used a contraceptive method; however, only one out of every ten women has used a modern method. Ever use is higher than the provincial average among

RIFT VALLEY PROVINCE

women with more than primary education, those who have worked (in the present or past) and those who want no more children. The relation between ever use and number of living children is erratic.

The contraceptive prevalence rate in Rift Valley Province is identical to the national rate (15 per cent). Women with no education, those who have never worked and those who want more children (soon or later) are less likely than other women to be using a contraceptive. Literacy status is closely related to the prevalence rate; only six per cent of illiterate couples are currently using contraception in contrast to 21 per cent of literate couples.

In addition to lack of exposure, i.e., those who are 'not sexually active/infertile' (19 per cent), lack of knowledge (12 per cent) and fear of side effects (10 per cent) are the main reasons for non-use given by non-users who are exposed and who know at least one contraceptive method.

Approximately 75 per cent of non-users knowing about family planning approve of its use, and a similar per centage intends to use in the future. Young women (15-24 years) and those who have never been in union tend to be somewhat more likely both to approve of contraception and to manifest a desire to use a method in the future than other groups.

Considering knowledge by method, the pill (61 per cent), injection (53 per cent), IUD (44 per cent), female sterilization (42 per cent) and periodic abstinence (rhythm) (36 per cent) are more widely known than other methods. Prolonged abstinence is the most frequently ever used method used (13 per cent) followed by periodic abstinence (rhythm) (12 per cent), the pill (7 per cent) and the IUD (3 per cent). Among the current users, the method mix is dominated by prolonged abstinence (28 per cent) and periodic abstinence (rhythm) (27 per cent), followed by female sterilization (13 per cent) and the IUD (12 per cent).

Method preferences among those who intend to use in the future show that injection (31 per cent), the pill (26 per cent), female sterilization (9 per cent) and periodic abstinence (rhythm) (9 per cent) are the most popular choices.

Availability (Tables 4.1-4.3)

In Rift Valley, 46 per cent of the women not using a modern method but knowing some method are aware of a family planning outlet. Literacy and knowledge of a family planning source are positively associated. Preferred outlets for the contraceptive supplies are hospitals (64 per cent) and clinics (32 per cent). One-third of these women have obtained family planning information or services from their preferred source. Around one out of every two women will need at least one hour to reach their preferred outlets, while only one out of every five women is within half an hour from a contraceptive source. More women (57 per cent) will use transport than walk to the outlet.

One out of every five women knowing some contraceptive but not using a modern method has ever been visited by a field educator. Of these,

only one out of every four women was visited by a field educator in the last three months. Afternoons and weekends are the preferred time and days for a field educator's visit.

At Risk (Tables 5.1-5.3)

In Rift Valley, 22 per cent of the women are at risk of an unwanted (12 per cent) or unplanned pregnancy (10 per cent). The total at risk increases gradually by age, with the increase being especially large between age groups 25-34 (21 per cent) and 35-49 (30 per cent). For the women in the age group 25-34, the proportions of women at risk of unwanted and unplanned pregnancy, respectively, are almost the same, while proportionately more women are at risk of unplanned pregnancy among the younger (15-24) than the older women (35-49).

Among women at risk, 32 per cent do not know about contraceptives, 85 per cent have never used a method, 66 per cent do not know any source, and 51 per cent do not intend to use a method in the future. The proportions in these categories are higher for the women at risk of unwanted pregnancy than for the women at risk of unplanned pregnancy.

NYANZA PROVINCE

General Characteristics (*Tables 1.1-1.4*)

A total of 970 women were interviewed in Nyanza Province. The surveyed sample is 91 per cent rural and 9 per cent urban.

The age distributions of the KCPS sample and of the census projections for the province are similar except for the age-group 20-24. The mean age of the KCPS respondents is 27.5 years; 49 per cent of the women are less than 25 years old, while 24 per cent are 35 years or older.

One-third of the women have not attended school, and around four out of every ten women are illiterate. Considering education by age, the results indicate a sharp decline in the educational level with age. Only 14 per cent of the women aged 35-49 have more than four years of schooling compared to 33 per cent of those 25-34 years old and 63 per cent of the women aged 15-24.

Two-thirds of the women have never worked. One-fifth are currently working, and the remainder have worked only in the past.

The literacy rate and the educational level of the spouses of the currently married women are much higher than those observed in all respondents. One out of every five husbands works in farming (one-half of them on their own farm), one out of every three is employed in a business, while almost one-half of the husbands are not working.

Nuptiality, Fertility and Reproductive Intentions

Nuptiality (*Tables 2.1-2.3*)

Marriage is more common among women surveyed in Nyanza Province than in other provinces; 77 per cent are currently married and only 16 per cent are reported as never married. Around one out of every four of the ever-married women first married before her 15th birthday, and two-thirds married for the first time before the age of 18.

Polygamy is very prevalent in Nyanza Province; 39 per cent of the currently married women have one or more co-wives. Even among younger women (15-24), one-fourth are in a polygamous union.

Fertility (Tables 2.4-2.6)

The mean numbers of ever born and surviving children for Nyanza Province are 4.0 and 3.0, respectively. One out of every three women has given birth to six or more children. Among women 25-34, the proportion of women who have more than five live births is 40 per cent, and it is almost twice for those in the age group 35-49. Completed fertility exceeds eight births.

The total fertility rate (8.2) is high. The proportion of women who were pregnant at the time of the interview---15 per cent---is the highest in Kenya.

Reproductive Intentions (Tables 2.7-2.10)

Around one out of every four currently married fecund women in Nyanza Province does not want to have more children in the future (12 per cent did not desire another child before their last pregnancy), approximately one-half of the women want to space, and one-fourth would like to have a child 'soon'. The desire to limit family size increases with age, exceeding 60 per cent among women aged 35-49.

With regard to a couple's reproductive intentions, 55 per cent of the couples agree that they want more children, while 8 per cent agree that they do not want any more. In the case of 12 per cent of the couples, the husband and the wife do not agree about their family size desires.

The mean ideal family size for women living in Nyanza Province is fairly high (5.9 children), and even never-married women want an average of nearly five children.

Knowledge and Use of Contraceptives (Tables 3.1-3.4)

Eighty-eight per cent of women in Nyanza Province know at least one contraceptive method. Women with more than four years of schooling, those who worked in the past, those whose husbands work and literate women married to literate husbands are likelier to know a method than other women. Those who could name a contraceptive method without prompting attribute their knowledge of family planning methods primarily to medical services (61 per cent), followed by the media (20 per cent) and field educators (7 per cent).

One out of every five women has ever used a method, but only one out of every two ever users has ever used a modern method. Very few (8 per cent) of the women in Nyanza Province are currently using a method. Levels of both ever use and current use are highest among women with more than primary education, those who wanted no more children before their last pregnancy, those whose husbands work in a business for someone else and among couples where both the husband and wife do not want more children.

The major reasons for non-use are: not sexually active/infertile (20 per cent), desire pregnancy (15 per cent) and lack of knowledge (12 per cent).

Among women knowing a method, but currently not using contraception, the proportions approving of family planning and intending to use in the future are the same (80 per cent). The intention to use in the future reaches a level of almost 90 per cent among young women (15-24), the never married, women with more than a primary education, women with two children, and those who want to space.

The pill (82 per cent), female sterilization (62 per cent), injection (62 per cent), periodic abstinence (rhythm) (54 per cent) and the IUD (53 per cent) are more widely known than other methods. Considering levels of ever use of specific methods, periodic abstinence (rhythm) is the most frequently used method (10 per cent) followed by the pill (7 per cent) and prolonged abstinence (6 per cent). Among current users, the method mix is as follows: the pill (29 per cent), periodic abstinence (rhythm) (23 per cent), female sterilization (14 per cent) and the IUD (11 per cent).

Preferred methods among those who intend to use in the future include the pill (36 per cent), injection (35 per cent), and female sterilization (13 per cent).

Availability (Tables 4.1-4.3)

In Nyanza Province, 45 per cent of the women not using a modern method but knowing some method are aware of a family planning outlet. Almost 90 per cent mentioned hospitals and 9 per cent cited clinics as the preferred source for contraceptives. More than half of these women have been to their preferred source to obtain family planning services or supplies. Two-thirds of the women say that it takes them at least one hour to go to the outlet. Only 15 per cent can reach the supply source within 30 minutes. Most of them (58 per cent) will walk to the outlet. One in seven says that there are reasons for not wanting to obtain contraceptives from the preferred source.

Only 10 per cent of the women knowing some contraceptive and not using a modern method have been ever visited by a field educator. Of these, one-third were visited by a field educator in the three months prior to the interview. Fifty per cent of the women who were asked about their preference as to the day for the field educator's visit said that they would like a field educator to visit them on Saturday or Sunday. The afternoon was the most frequently preferred time of day to be visited followed by the morning and the evening.

At Risk (Tables 5.1-5.3)

In Nyanza Province, one in five women interviewed is at risk of an unplanned or unwanted pregnancy. The largest group at risk is in the 25-34 age cohort; one-fourth of these women are at risk. The smallest group at risk is in the 15-24 cohort where only 16 per cent are at risk. The risk of unwanted pregnancy increases with age while the risk of an unplanned pregnancy decreases with age.

NYANZA PROVINCE

Among women at risk, eight per cent do not know about contraceptives, 83 per cent have never used any method, 51 per cent do not know any family planning outlet, and 23 per cent do not expect to use a method in the future.

WESTERN PROVINCE

General Characteristics (Tables 1.1-1.4)

A total of 1,001 women were interviewed in Western Province. The surveyed sample is 90 per cent rural and 10 per cent urban.

The age distributions of the KCPS sample and of the census projections for the province are similar with the difference exceeding 3 per cent only for the age group 20-24. The mean age of the respondents is 28; 47 per cent of the women are less than 25 years old while 28 per cent are 35 years or older.

One-third of the women are illiterate. The results indicate a decrease in a woman's educational level with age. Only 22 per cent of the women age 35-49---compared to 37 per cent of those 25-34 years old and 77 per cent of the women aged 15-24---have more than four years of schooling.

Three out of four women have never worked. One in seven is currently working, and one in ten has worked only in the past.

The literacy rate and the education level of the spouses of the currently married women are higher than those observed for all respondents. More than one-third of the husbands work on a farm (one in five owns his farm), while 27 per cent of the husbands are engaged in non-farming occupations. The remaining husbands are not employed.

Nuptiality, Fertility and Reproductive Intentions

Nuptiality (Tables 2.1-2.3)

More than six out of ten women are currently married in Western Province, while almost three out of ten women are reported as never married. Almost all ever-married women first married before their 25th birthday, and more than 50 per cent were less than 18 years old when they married for the first time.

Polygamy is fairly prevalent in Western Province; 28 per cent of the women are in polygamous unions. More than one in five women in the age group 15-24 has one or more co-wives, and one-third of the women aged 35-49 are married to the husbands who have more than one wife.

Fertility (Tables 2.4-2.6)

The mean number of ever born and surviving children for the women interviewed in Western Province are 4.1 and 3.2, respectively. One-third of the women have had six or more live births. The proportion of the older women (35-49) who gave birth to more than 5 children is 85 per cent. Completed fertility exceeds nine births.

Current fertility levels are also high. The total fertility rate is 6.3. Fourteen per cent of the women were pregnant at the time of the interview.

Reproductive Intentions (Tables 2.7-2.10)

Around one in three currently married fecund women in Western Province does not want to have any more children. In fact, 15 per cent did not want to have more children before their last pregnancy. Almost 30 per cent want to space, while 23 per cent want their next (first) child within a year or so. The desire to limit the size of the family increases with age, with almost 60 per cent of women aged 35-49 saying that they do not want another child.

The mean ideal family size for women living in Western Province is 6.0 children. Currently married women desire larger families (6.5 children) than never married women (4.7 children). Among couples in which both the husband and wife are illiterate the mean ideal family size is seven children, while it averages one child less when both the woman and her spouse are literate.

Knowledge and Use of Contraceptives (Tables 3.1-3.4)

The overall level of knowledge of contraceptive methods is low in Western Province; only 69 per cent know at least one method. Knowledge levels vary with age; eighty-two per cent of the women aged 25-34 know some method, while only 60 per cent among younger women and 71 per cent among older women know at least one method. Those who work, those who wanted no more children before their last pregnancy, those who are literate or who are married to literate husbands, and those with two or more children are more likely than the average woman to know about family planning. Of the women who could name a contraceptive method spontaneously, 59 per cent received information about contraceptives from medical services, 14 per cent from media, and seven per cent from field educators.

The level of ever use of contraceptives is low in Western Province. Overall, only 14 per cent of the women have ever used a method, with 9 per cent reporting having experience with a modern method. Ever use is higher among women over 24 years, among those with more than eight years of schooling, among those who have worked and among those not wanting more children before their last pregnancy than among other groups. The

most notable differences in ever use are observed in relation to the literacy of the couple. When both husband and wife are illiterate, the ever use rate is six per cent, in contrast to an ever use rate of 22 per cent among literate couples.

The level of current use in Western Province is the lowest in Kenya; only 4 per cent of women are using a family planning method. The major reasons for non-use are: not sexually active/infertile (22 per cent), lack of knowledge (12 per cent) and desire pregnancy (10 per cent).

The level of approval of family planning and of the intention to use in the future among non-users knowing contraceptives presents a contradictory picture. A somewhat greater proportion of women intend to use in the future (81 per cent) than say that they approve family planning (70 per cent). The intention to use in the future is higher than the provincial average among women who have never married, who are younger than 35 years, who have 5-8 years of education, who did not want a child before their last pregnancy, and who want to space.

The results show that the pill (62 per cent), injection (52 per cent), the IUD (47 per cent) and female sterilization (37 per cent) are the most widely known methods. The pill also is the method most frequently ever used (7 per cent), followed by periodic abstinence (rhythm) (4 per cent), prolonged abstinence (4 per cent), and the IUD (3 per cent). Among the small number of current users, the three most widely used methods are: pill (34 per cent), the IUD (31 per cent) and periodic abstinence (rhythm) (10 per cent).

Method preferences among those who intend to use in the future show that injection (44 per cent) and the pill (33 per cent) are the most popular choices.

Availability (Tables 4.1-4.3)

In Western Province, 45 per cent of the women not using a modern method but knowing some method know a family planning outlet. The women who know an outlet most often mention hospitals (82 per cent) and clinics (17 per cent) as the preferred source for contraceptive methods. One out of every five non-users knowing a method has used the source to obtain family planning information or services. Only 20 per cent of these women can reach the outlet they named within 30 minutes, while one out of every two of them expect to spend one hour or more to go to the source. Most of them (70 per cent) would walk to the source. About one out of every seven women thinks that there are reasons not to use the source that they have mentioned.

Only 11 per cent of the women knowing contraceptives and not using a modern contraceptive method have ever been visited by a field educator. Of these women, only 30 per cent have been visited by a field educator in the last three months. Almost equal proportions (around 20 per cent) prefer the field educator to visit them in the morning or afternoon while 15 per cent prefer evening visits. Thirty-one per cent have no preference as to the time. Among those expressing a preference as to the

day the educator should visit, Saturdays and Sundays are preferred most often.

At Risk (Tables 5.1-5.3)

One out of every five women is at risk in Western Province of an unwanted pregnancy (13 per cent) or unplanned pregnancy (7 per cent). Only nine per cent of the women age 15-24 are at risk, largely of an unplanned pregnancy while 29 per cent of women in the 25-34 and 35-49 age groups are at risk. Among women 35-49 years old who are at risk, almost all are at risk of unwanted pregnancy while, in the age group 25-34, only slightly more than one-half of the group at risk are at risk of unwanted pregnancy.

Among women at risk, 21 per cent do not know about contraceptives, 89 per cent have never used a method, 65 per cent do not know an outlet and 40 per cent do not intend to use a method in the future. The lack of interest in using in the future is greater among those at risk of unwanted pregnancy than among women at risk of unplanned pregnancy.
